In many instances pulmonary tuberculosis progresses to a fatal termination without distribution of tuberculous foci beyond the pleuræ. Such patients die from exhaustion, hemorrhage, or sepsis, and seem to acquire an immunity to the effect of tubercular toxemia. In my experience when subsequent distribution of foci in regions more or less remote from the initial lesion has occurred, the development has been as follows:

Involving the pleura or pericardium or both in 90 cases; the larynx in 33; the cervical or axillary lymphatics in 10; the intestinal canal in 6; the endocardium in 6; the kidneys in 5; the peritoneum in 1; the skin in 1; the mesenteric glands in 2; the tonsils in 1, and the nose and pharynx in 1. In 94

of these cases the tuberculous process at some time during the course of the disease, usually in the beginning, has involved the lungs.

The genito-urinary system, exclusive of the kidneys, has been involved in the tubercular process in two cases, one in a female 12 years of age, in which the bladder, urethra, and vagina were involved (as shown by necropsy), and one in a male between 30 and 40 years of age, in whom the right testicle and inguinal lymphatics became involved, and who is still living after surgical removal of the affected organs.

Of complications in tuberculosis of a non-specific character, the most important in my experience have been lobar pneumonia and acute or chronic diffuse parenchymatous nephritis. Eleven patients have had intercurrent lobar pneumonia, in two of whom, as will be noted below, it was the immediate cause of death. Acute diffuse parenchymatous nephritis complicated two cases, the patients making good recoveries from the complication. Five had chronic diffuse parenchymatous nephritis, which persisted to the fatal termination, although not being the immediate cause of death, except in two cases. Intercurrent attacks of acute bronchitis, laryngitis, and inflammatory affections of the upper air passages have been of frequent occurrence, especially during the winter and spring months. As a rule, they have not been of serious moment, and have been as readily amenable to treatment as though occurring in non-tubercular individuals.

When pyrothorax occurs in tuberculosis it is usually from an infection other than that of the specific bacillus; in the cases in which I have made cultures, streptococci and staphylococci, and in one case pneumococci, have always been found, and I have regarded this complication as a pyogenic wound infection. It has never given me serious trouble in itself as a complication, and only in one instance was it necessary to drain from the outside. I have never seen it occur in tuberculosis except late in the disease, when adhesions already formed kept it walled off until bronchial drainage was established.

Pregnancy complicating tuberculosis becomes a serious matter, and is not as uncommon an occurrence as might be imagined. I shall speak of this more fully under "prognosis." It has complicated four of my cases. Endocardial complications of a non-tubercular type occurring in the course of the disease are, in my experience, usually of septic origin and contribute to the causes of death from exhaustion. It is highly probable that in my two cases complicated by acute nephritis, there was also an endocarditis, but heart signs of pathognomonic nature were unobtainable, and as both patients recovered from the complication and are still alive no autopsy has been made. Mitral lesions, no doubt of inflammatory origin, have complicated two of my cases. One patient has made an apparent recovery from the tubercular lesion; the other has passed from my observation. I have no history of other valvular lesion occurring as a complication in tuberculosis.

Fistulæ in the neighborhood of or connected with the rectum have complicated two of my cases, and have added much to the discomfort in both instances.

I would in this connection like to call attention to two more or less persistent phenomena which I have observed in this disease. They can scarcely be termed complications, but are sufficiently often present to indicate an association with the disease. That most commonly noted, and which has been invariably associated with the more chronic forms of the disease, is the peculiar "clubbing" of the terminal phalanges of both fingers and toes, a condition often noticed also in chronic valvular disease. The fluoroscope shows this to be less an enlargement of the bone than of the nails and soft parts, although the bone is itself somewhat enlarged. This phenomenon must have some connection with that obscure condition described by Pierre Marie as hypertrophic pulmonary osteo-arthropathy.

The other phenomenon mentioned is that very striking pigmentation of the exposed skin surfaces of the body; thirty-one of my patients demonstrated it; description is unnecessary, as all who have seen much of pulmonary tuberculosis will have noticed it. I believe it is regarded as due to deposit in the skin of waste pigments retained in the circulation.

The immediate cause of death in my experience has been somewhat difficult to define in most instances. I use the term "asthenia" for want of a better, but fully appreciate its lack of definition. It is, perhaps, better than "heart failure," although conveying scarcely more significance. The immediate cause of death in 34 cases was asthenia; in 2, hemoptysis; in 2, lobar pneumonia; in 2, uremia; in 1, sepsis, and in 1, acute miliary tuberculosis, making a total of 42 deaths. Since this report was written, however, I have news of the death of one more of these one hundred patients from laryngeal stenosis, a rare, though not unknown, cause of death in tuberculosis.

The average duration of the disease in my fatal cases has been, as nearly as I could discover, something under two years, but this period applies only to the duration of the active progression of the disease. I am convinced that a tuberculous focus in which may be found live bacilli can, and in many apparently acute cases does, exist for many years

without giving its host sufficient discomfort to occasion discovery. In these cases appearances often conceal the true condition of things, and a diagnosis of primary acute tuberculosis is made and borne out by a rapidly fatal termination.

The features which have given me the most reliable data upon which to base a prognosis have been pulse and temperature, degree and rapidity of emaciation, condition of the organs of elimination, and condition of the digestive system. I think I have mentioned them in the order of their importance in a prognostic sense; of course, the locality of the primary lesion and the amount of involvement, together with existing complications, are of primary importance. It has been my experience that a small, compressible pulse persisting above 120 is usually indicative of progressively fatal cases, while a fairly strong pulse remaining below 100 is found in cases amenable to treatment. A temperature reaching 102° to 104° F. once or twice during the day, with remissions or intermissions and profuse diaphoresis, either associated or not with a rapid pulse, has been of unfavorable import with me, and has usually marked the onset of an uncontrollable pyogenic infection. When an acute miliary tuberculosis supervenes upon a chronic condition the temperature wave is not marked by such deep remissions, and there is less diaphoresis, although the temperature may reach much higher points than in the ordinary streptococcic and other pyogenic infections.

Emaciation, which has progressed rapidly to a considerable degree has, in my experience, indicated an unfavorable prognosis, although there have been numerous exceptions to this rule. When the weight ceases to fall and responds to forced alimentation, in the absence of other unfavorable signs I have found improvement more or less constant to follow. On the other hand, I have witnessed a gain in weight of nearly a pound per day in cases which were progressing to fatal termination, but this is exceptional. Acute nephritis, if at all severe and when of an infectious origin, must of necessity be a serious complication, although both of my patients recovered, probably because the affection was localized within narrow limits. The presence of chronic Bright's disease would make the prognosis necessarily fatal, although as to time it shortened life twice, and seemed not to materially do so in the other three cases of mine. The condition of the skin as an eliminative organ is of important significance in prognosis. In one of my cases intercurrent chicken-pox contributed largely to a fatal termination. Diarrhea, on the one hand, and persistent constipation on the other, have complicated unfavorable cases. Depraved digestion, from whatever cause arising, is a serious symptom in a disease in which nutrition is the main therapeutic consideration, and when persistent has materially contributed to an unfavorable termination. regnancy in any stage of tuberculosis has invariably increased the activity of the disease, all but one case having terminated fatally within a few months of parturition, but my patients became pregnant in the latter stages of the disease. I have no statistics on pregnancy in early tubercular disease. Mitral disease has appeared in my two cases to have had a beneficial effect upon the tubercular process, which I believe is the rule.

The amount of expectoration and the number of tubercle bacilli present therein has, within reasonable limits, no prognostic significance whatever. Sputum from a very favorable case is often found to contain innumerable bacilli in every field, while some of the most vicious cases in my experience have produced very little expectoration and only few bacilli, sometimes necessitating a long hunt to find them at all. The presence of bacilli serves to clear up the diagnosis beyond all doubt, but the number found has little significance in prognosis. Likewise examinations of the blood made at stated intervals have given me no reliable data upon which to form a prognosis. It has lately been demonstrated that Ehrlich's diazo reaction in urine, when obtained in tuberculosis, indicates almost invariably a rapid and fatal course of the disease, a rule which applies to any stage of tuberculosis.

Primary development or secondary extension of tuberculosis into the left lung, especially into the lower lobe, has been followed by more rapidly fatal results, and left pulmonary tuberculosis has been less amenable to treatment than when the right side has been affected, other things being equal. Primary infection occurring after the sixtieth year has been rapidly fatal, and very little influenced by treatment, but when a reinfection occurs at an advanced age from an old latent focus I have found a tendency to self-limitation quite marked, a fact which is contradistinct from the tendency in early life, when the reinfection or auto-infection arising from a diseased lymph-gland or joint is usually rapidly fatal.

That immunity to tubercular toxemia may be acquired by some individuals I have seen demonstrated in many instances, a very unstable immunity, however, which any intercurrent complication may destroy. In one instance coming under my observation several years ago, and which is not included in the above group, a man fifty years of age had had pulmonary tuberculosis for thirty years. Bacilli were demonstrated in the sputum as soon as Koch's methods of demonstration were practised in

this country. After the first year of the disease he appeared to regain a normal standard of health, which continues to the present time, notwithstanding that there is an area of dulness over the upper lobe of one lung and bacilli are still to be found in the sputum. Such immunity, however, is exceedingly rare, although I believe it would be more often obtained if other pathogenic infection could be excluded.

EXTERNAL ESOPHAGOTOMY FOR IMPACTED FOREIGN BODY IN THE ESOPHAGUS, LOCATED BY THE X-RAY.[1]

BY JOHN C. McCOY, M.D.,
OF PATERSON, N. J.

SINCE Goursald, in 1783, first removed by external incision an impacted body from the esophagus, the operation has been performed upward of 175 times, most of the subjects having been operated upon during the last fifteen years. Bones, artificial teeth, and coins constitute the majority of impacted bodies calling for operative interference. In the entire number of patients operated upon up to the present time the mortality has been twenty-two per cent. This includes those cases in which the impaction has been of long standing, as in Dr. Furner's case, in which he removed by an incision in the posterior wall of the esophagus a dental plate which had been lodged there for nearly five years, and those cases in which the impaction has been of but a few hours' duration. The mortality during the period of aseptic surgery has been lowest in those cases in which there has been an early operation, in which patients the tissues have not been contused and lacerated by frequent and prolonged efforts to dislodge the body by means of the various esophageal instruments, and has been highest in those cases where some time has been allowed to elapse between the impaction of the foreign body and its removal.

After having looked over the literature of the subject I am inclined to believe that in many of the cases better results might possibly have been obtained had the operation been resorted to at an early hour after the impaction had become complete, rather than wait a considerable length of time and then operate when the tissues are partially devitalized and the field of operation perhaps infected. When one is sure that the impaction has become complete the rule should be to operate at once. Nothing is to be gained by procrastinating, as under proper conditions the operation is not difficult and the results are most gratifying.

The case which it is my privilege to report occurred in the practice of Dr. W. K. Newton of Paterson, N. J. The history is as follows:

On May 1, 1897, C. D., male, aged seven years, was suddenly seized with severe retching and coughing. His mother upon questioning the boy learned that he had swallowed a small tin whistle with which he had been playing. Dr. Newton saw the child two hours after the accident occurred, at which time he was suffering from rather marked dyspnea and absolute inability to swallow even water. At 8 P.M., four hours after the accident, the dyspnea had become more marked. There was slight cyanosis, the respirations being labored and rapid. Edema was present under the eyes, and there was complete inability to swallow. The tongue was somewhat swollen and the pharynx markedly congested. Palpation elicited a slight bulging in the median line of the throat about an inch above the sternal notch.

Appreciating the shape of the foreign body the patient was placed under complete chloroform narcosis and a long coin-catcher was passed down the esophagus. The impact of the instrument against the metallic body could be readily felt, and after some little effort it gripped the body firmly, but slipped off when traction was made upon it and no further hold could be obtained. After this manipulation the prominence which had been felt just above the sternum could no longer be distinguished. The breathing at this time became much less labored and in a short time the child was able to swallow liquids, although with considerable difficulty.

Thinking that the whistle, which had been lodged at right angles to the esophagus, was now located parallel to it (it having been tilted into this position by the coin-catcher), which fact would account for the disappearance of the dyspnea, owing to the pressure being taken off the trachea, and to his ability to swallow, on account of the lumen of the esophagus not being entirely occluded, a basket-shaped catcher was made of medium-sized copper wire and an endeavor was made to pass this beyond the foreign body, hoping to engage it as the instrument was withdrawn. All efforts to reach the body were unsuccessful, and owing to the congested and swollen condition of the pharynx, further manipulation was discontinued.

The following morning, the breathing being somewhat impaired and dysphagia rather marked, although the child was able, with some little effort, to swallow milk and egg, there was a feeling of uncertainty as to whether the foreign body might not have been pushed on into the stomach and the dysphagia the result of our efforts of the preceding night to dislodge it. That afternoon an X-ray exposure was made from the chin to the umbilicus, and it distinctly showed the whistle lodged transversely in the median line of the neck about an inch above the sternal notch The boy was transferred to the private ward of the hospital, and at 10 o'clock the following day, forty-one hours after the impaction of the body, was operated upon.

An incision was made from the lower border of the cricoid cartilage to the upper margin of the

[1] Read before the Medical Society of New Jersey, at Asbury Park, N. J., June 29, 1898.

sternum, extending along the anterior border of the left sternomastoid muscle. The muscle was drawn to one side, the sternal attachment of the sternomastoid divided so as to afford more room, and the dissection was then carried down to the large vessels which in their sheath were drawn outward by a short retractor. The trachea and thyroid glands were drawn down inward by a second retractor. The esophagus, with the recurrent laryngeal nerve lying upon it, was next exposed. The esophagus with the adjacent tissues both above and below the foreign body were considerably swollen and congested, and at the side where the whistle was in contact with the esophageal wall the tissues were decidedly thinned, showing the utter futility and great danger which would have resulted from an endeavor either to draw the body up or to force it down. In either case the esophagus could have hardly escaped rupture and the tissues contusion and laceration.

An incision an inch long was next made on the anterior surface of the esophagus a trifle to the left of the median line and directly over the foreign body. A fine silk ligature was then passed through the edges of the esophageal wall in order that the wound might be held open. Then a tenaculum was introduced into the small opening of the whistle, and the whistle rotated until it assumed an anteroposterior direction and was then readily withdrawn. The tissues were then thoroughly cleansed with boracic-acid solution, the wound in the esophageal wall closed with interrupted sutures of fine catgut placed closely together, and the superficial wound closed with interrupted sutures of silk. Small pads of iodoform gauze were placed over the wound and a bandage applied snugly about the neck so as to exert considerable pressure over the wound in order that counter-pressure might be exerted during the act of swallowing. There was only slight shock and absolutely no nausea or vomiting following the operation. Small portions of sterilized water were administered as soon as the patient was able to swallow and continued at intervals of every half hour to an hour. At the end of twenty-four hours sterilized milk was administered, and after each feeding a few sips of sterilized water were given in order that the esophagus might be thoroughly cleansed. A small opening appeared in the lower angle of the wound on the third day, and when the patient swallowed a portion of the fluid found its way through this opening. Firm pressure upon the wound when the patient was taking nourishment remedied this entirely. The fistulous tract closed in seven days, and on the sixteenth day the patient left the hospital. He was able to take solid food and was apparently in good health. At no time after the operation did he have a temperature above 99° F.

In the light of this case I would draw the following conclusions:

FIG. 1.

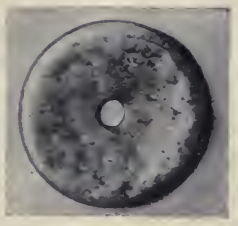
Skiagraph of small tin whistle lodged in the esophagus of a child aged seven years. Removed by external esophagotomy.

1. A foreign body impacted in the esophagus for more than twelve hours, particularly if it be known to have edges liable to inflict injury upon the tissues if traction be made upon it, should be removed at once by external incision.

2. The prolonged and continued use of the various esophageal instruments should be condemned, as the tissues are usually contused and lacerated by their use and their vitality and resisting powers lowered.

3. When the tissues have not been lacerated and the impaction has not been of long duration,

FIG. 2.



Tin whistle removed by external esophagotomy. (Exact size.)

the tissues appearing healthy, the esophagus should be closed with fine catgut and the external wound closed completely.

4. It is better to give small portions of sterilized water at an early hour after the operation in order that the esophagus may be kept as clean as possible. Feeding by tube or per rectum is usually uncalled for. At the end of twenty-four hours liquid nourishment may be given, and after each feeding a few sips of sterilized water should be administered so that the esophagus may be again cleansed.

*THE GONOCOCCUS.**

BY WILLIAM C. MITCHELL, M.D.,
OF DENVER, COL.;
ASSOCIATE PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF DENVER; CITY BACTERIOLOGIST, DENVER HEALTH DEPARTMENT; BACTERIOLOGIST TO ST. LUKE'S HOSPITAL.

SIX years after the discovery of the gonococcus by Neisser, Bumm, in 1885, succeeded in cultivating this organism artificially, and these pure cultures inoculated into the human urethra called forth typical cases of gonorrhea. The gonococcus is a strict parasite and until quite recently its cultivation artificially was attended by considerable difficulty. It refused absolutely to develop on the ordinary media and demanded that the whole, or at least a part of its nourishment, should be human blood-serum. Bumm's first cultures were obtained by inoculating gonorrheal pus on solidified human blood-serum obtained from the placenta; but Bumm's method did not permit of the isolation of the gonococcus except in a very imperfect manner as his medium was solid, thus very frequently allowing other micro-organisms present to grow so rapidly as to prevent the development of the gonococcus. So much was this true that he did not believe it possible to cultivate the gonococcus from pus obtained from the genital organs of the female as the other numerous organisms present would outclass it. It was then that Wertheim[1] came forward with his plan of cultivating this organism by means of the plate method, thus permitting of the isolation of the gonococcus even when numerous other organisms were present.

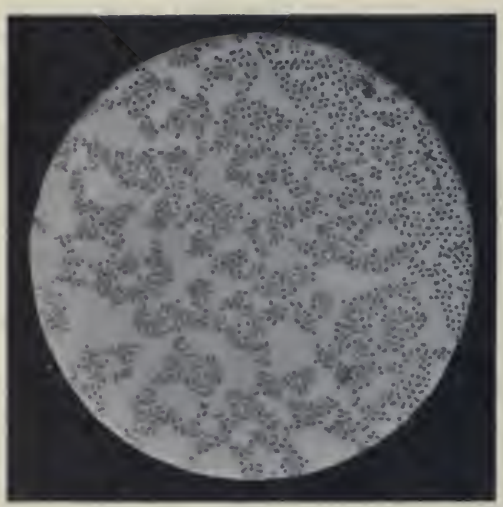
Wertheim's method consists in inoculating sterile liquid human blood-serum (original, first, and second dilutions) with the material to be examined. The same amount of ordinary agar is then added to each tube, the contents being carefully mixed and then plated. Wertheim's experiments have passed down as classics in the history of this organism and he gives in detail the results obtained by the inoculation of five different human urethras with pure cultures obtained by his method[2]. The cases left nothing wanting from a clinical standpoint, a period of incubation for two days or longer, abundant purulent discharge containing typical gonococci, and lasting in no case less than four weeks and in one case more than two months.

Bockhart substituted with success for serum thus obtained the exudate of a pericarditis. Other of the pathologic sera have been successfully used, as hydrocele fluid, pleuritic and ascitic effusions, the latter, according to Sée, being the best adapted of all the sera, not the least of its advantages being the ease and the great quantities in which it may be obtained.

It had been attempted by different observers to substitute for human serum that obtained from the lower animals, but with little success until Wasserman[3] introduced the use of hog-serum into the technic. As the pure culture which is here shown was obtained by Wasserman's method it may be well to state it briefly in detail. Fifteen c. c. of hog-serum, diluted with from 30 to 35 c. c. of water, is placed in an Erlenmeyer flask. Two to 3 c. c. of glycerin, and .8 grm. (2 per cent.) of nutrose is then added. This last preparation was introduced into commerce by Salkowski under the above name and is a sodium-casein phosphate and among other things has the property of preventing serum from solidifying when heated over a flame. The mixture is then cooked over a flame for from 20 to 30 minutes. When ready for use it is mixed with equal parts of ordinary two-per-cent agar. The mixing must take place at between 50° and 60° C. and not at boiling temperature. By this method I have suc-

* Read before the Denver and Arapahoe Medical Society, October 11, 1898.

ceeded in cultivating the gonococcus without difficulty, although with the above dilutions of the serum it was not found that the serum coagulated either with or without the addition of the nutrose. The developing colonies correspond very closely to those described by Wertheim, especially the superficial ones. These show a slight, compact, central portion, from which extends a slender, transparent, and uniform zone of slight dimensions. The majority of the colonies are in the depth of the medium and are compact and of a round, oval, or irregular form. In "fishing" a colony to examine on the cover-glass the forms are not seen so well as by making an impression preparation. In the impression preparation the forms can be observed well differentiated,



Gonococcus, pure culture, by Wasserman's method. (Zeiss homo. immer., 1–12, prog. ocular No. 4.)

showing the characteristic morphology of the gonococcus with the unstained central slit. Of course, these colonies lose their stain completely when treated by the Gram method.

It is not to be supposed, however, that the practising physician will undertake the cultivation of this micro-organism as it is beyond the reach of one not supplied with proper laboratory equipments and training, but as it may with almost absolute certainty be differentiated by aid of the microscope, with proper methods of staining, the difficulty in cultivation has not interfered with its usefulness as an aid in clinical diagnosis.

Unstained gonorrheal pus under the microscope gives an interesting picture. Scattered throughout the field may be seen refractive bodies grouped in couples, true diplococci. Some of these bodies may be seen in motion, and the motion most frequently to be observed is a rotary one in which the cocci often unquestionably change their position so that the motion cannot properly be regarded as Brownian or molecular, as it was by Bockhart, but is a representation of the vital activity of the organism.

The finer structures of this micro-organism are best revealed by a stain of delicate selecting power, such as Löffler's methylen-blue. The gonococcus is seen to be composed of two symmetrical bodies uniformly rounded on their dorsal surfaces and having their flattened surfaces facing each other and separated by a slight uncolored slit or fissure. According to Neisser and Bumm division takes place perpendicularly to the median slit, giving rise to groups of four and even eight cocci. These sarcinæ forms are most abundant and may be best observed in young, actively growing cultures. This mode of multiplication gives rise to a characteristic grouping of the gonococcus differing from the staphylococci grouping and yet difficult to describe. This grouping, the *amas* of the French, constitutes one of the recognized characteristics in the identification of this organism.

Another of the characteristics of the gonococcus is its situation within the pus-cells. Whether this is due to the active penetration of the cell by the gonococci, or whether the white cells incorporate the gonococci by virtue of their phagocytic action is still a question. The fact remains the same, however, in most if not all of the cases, that in the end the cell is vanquished by the gonococci, which multiply within its substance until they cause its disintegration. One meets with these disrupted cells quite frequently. Often only the fragment of a nucleus is visible, around which may be seen the gonococci with their characteristic grouping, occupying a rounded space, and no sign of the cell itself visible.

The most important characteristic of the gonococcus is that it decolorizes when treated by the Gram method, and this is so important that the technic may be mentioned in detail. The preparation, dried and fixed in the usual manner, is immersed a few seconds in Ehrlich's anilin-water gentian-violet solution, prepared by adding 100 c. c. of anilin-water (5 c. c. of anilin-oil to 100 c. c. of water), after being filtered, to 11 c. c. of a solution of gentian violet. The coloration of the specimen is instantaneous. Then, without washing, the surplus stain is drained off and the cover-glass immersed about half a minute in a solution containing 1 part of iodin, 2 parts of iodid of potassium, and 300 parts of water. It is then washed in two baths of absolute alcohol until no more blue color is given off.

This last step, with thin, evenly spread cover-

glasses, takes from one to one and a half minutes. The gonococci in the preparation are absolutely decolorized, while the pus-cocci and other diplococci retain their stain. This is a very valuable and practical method of differentiating the gonococcus from other organisms which may resemble it. The Gram method does not give as pretty a picture as the Löffler stain on account of the unavoidable sediment it leaves in the preparation, but accuracy in diagnosis is what should be sought for. It is convenient to divide the above procedure into two steps, the slide first being examined stained only with the gentian violet. This reveals the gonococci, if they are present, with their typical morphology, only they appear thicker and plumper than with Löffler's stain. If such diplococci are found to be present the slip is then placed in the iodin mixture and afterward in absolute alcohol. On reexamination, if the organisms first observed were gonococci, they will be found to have given up their stain to the alcohol; if they remain stained they positively are not gonococci.

Except in acute cases of very recent origin I do not believe one is ever justified in making a diagnosis of gonorrhea by the Löffler-stain method alone. In chronic cases the Gram method should never be neglected. The question becomes a very serious one when a patient, having had gonorrhea, it may be many months previously, presents himself for an opinion as to whether or not he may marry. In such chronic cases it is often possible to observe the pus-cocci embedded in the pus-cells in such a manner that if regarded from the standpoint of their morphology alone they would be considered gonococci, but when tested by the Gram method they remain as darkly stained as before the iodin and alcohol solutions were added. In chronic cases not only should the gonorrheal threads in the morning urine be examined, but also the suggestion of Heim's is a good one, namely, to centrifuge the urine and examine the sediment. One occasionally finds a few pus-cells containing typical gonococci by this method when they escape observation by the other method, that is, in examining the threads alone.

To sum up the diagnosis of the gonococcus by the microscopical examination, then, we have the following: (1) Diplococci about one micromillimeter in size, of a coffee-bean shape, and situated in characteristic grouping. (2) The intercellular position. (3) The complete decolorization by the Gram method. No one of these characteristics taken alone is a sufficient guarantee for considering a given organism as the gonococcus, but together they give as nearly absolute a criterion as is possible without the culture and the reinoculation of a healthy urethra.

None of the above divisions has remained free from criticism. The characteristic grouping has remained the least so, for as has been so strongly insisted upon by Sée[4] it is scarcely to be found with any other organism. With reference to the intercellular position there are, of course, other cocci to be found within pus-cells which are not gonococci, but almost without exception they retain their color when treated by the Gram method. In a criticism of the Gram method Hogge[5] states that he regards the method as unreliable, for by varying the time of the staining and the decolorization one obtains varying and untrustworthy results. But this objection should have little weight as by varying the time with the ordinary solutions for staining the tubercle bacillus one may also obtain uncertain results, as for example, too short a straining with the carbol-fuchsin and too long an exposure to the acid methylen-blue, yet by a proper timing of those two stains the results are absolutely trustworthy.

Perhaps the most serious objections that have been raised to the Gram method are those by V. Hibler[6]. He found that by subjecting fresh gonorrheal pus to "secondary changes," such as desiccation under certain conditions, the gonococcus at times gave up its stain and at other times retained it. He also ascertained that by placing such pus in urine for from ten to twenty hours the reaction was also uncertain and, according to him, unreliable. But as Sée justly remarks, whatever may be true of the gonococcus when placed under such unnatural conditions with reference to the Gram method, the incontestable fact remains that when taken in its natural and unaltered condition the gonococci in gonorrheal pus will always give up their stain when properly treated by the Gram method. Hibler also found that under certain unnatural conditions the staphylococcus pyogenes aureus would give up its stain when treated with the iodin solution and alcohol, but the same objection to his methods and observations would also apply here. Lastly it must be mentioned that Bumm records that forms have been found in the healthy urethra that morphologically resemble the gonococcus and yet gave up their stain to the alcohol. These exceptions are so extremely rare, however, and have so seldom been met with by other observers that they should have but little, if any, influence in deciding a diagnosis.

CLINICAL MEMORANDA.

THE PRACTICAL TREATMENT OF SCALDS AND BURNS.

By N. D. CHAPMAN, M.D.,
OF LUDLOWVILLE, N. Y.

CASE I.—Girl, aged sixteen years; burned on the back extensively. She was treated with dry dressings, bismuth subnitrate being used. After a few weeks she died, just before death having symptoms of bismuth poisoning.

CASES II. and III. were severe burns from lightning. The patients were first treated with dry dressings, and the mere dressing of the burns caused so much pain that one screamed with fright when she saw me coming. Unguentine was substituted and both patients made a rapid recovery.

CASE IV.—Frank W., aged twenty-five years, single, on December 28, 1895, while engaged in raking salt from a vat made a misstep and fell backward into the scalding brine, striking on the buttocks, one arm and side of legs, all of which were immersed, together with both wrists, and the lower half of the back and abdomen. He was quickly removed and his clothing cut from him, and was then wrapped in a blanket. Upon my arrival I found him in great agony. I gave a hypodermic injection of morphin to quiet pain, and strychnin and digitalis internally, and applied heat externally to counteract shock. I dressed the scalded area with soft muslin saturated with carbolized linseed oil and lime-water. After six hours the dressings were removed and the blisters evacuated, the latter having formed extensively wherever the skin had been scalded. The scalds were again dressed as before, and morphin, cardiac stimulants, and diuretics were given. The patient's temperature was 102° F., and his pulse 120. He was very restless and delirious at night. These symptoms continued for nearly ten days, then gradually subsided. The dressings were changed three or four times a day, and during the interval were kept moist with the oil solution. The removal of the dressings caused a great deal of pain. They were very offensive. The oil was used so extensively that it soiled the bedding and furniture beyond repair. On the tenth day the oil dressings were exchanged for unguentine, spread on narrow strips of muslin. The patient experienced great relief and the wounds were dressed much more quickly and easily. It was found that the dressings did not get dry and hard. The sloughing which had been present ceased and also the odor. The unguentine acted speedily and effectually, restoring the destroyed tissues, and in places where granulation tissue had appeared it cauterized and healed simultaneously. The patient made an uneventful recovery at the end of thirty days and has been free from the complications attending other methods of treating burns and scalds.

Some of the advantages of unguentine as an ideal dressing may be summarized as follows: (1) Easy to apply. (2) Great relief to patient, acting as a sedative, cooling, and non-irritating. (3) It does not dry out so quickly, and consequently the dressings do not have to be changed so often. (4) Rapid cicatrization. (5) When used early it prevents formation of granulation tissue. (6) It is non-toxic. (7) Patients recover more quickly under the unguentine treatment than any other. (8) Prevents the necessity of skin-grafting in a good many cases by hastening the reparative process. (9) It is much more convenient, neat, and practicable.

ACUTE PULMONARY EDEMA SUCCESSFULLY TREATED BY VENESECTION.

By H. B. WHITNEY, M.D.,
OF DENVER, COL.;
PROFESSOR OF MEDICINE IN DENVER UNIVERSITY; VISITING PHYSICIAN TO THE ARAPAHOE COUNTY HOSPITAL.

IN most of the articles on acute pulmonary edema venesection is spoken of as a proper treatment, though often with too little emphasis. Since practical illustrations of this truth are infrequent, the following case may be of interest:

Mrs. H. E. C., aged twenty-five years, of Cripple Creek, was referred to me by Dr. B. F. Cunningham for heart disease. She first consulted me at my office on October 6, 1898. There was a history of inflammatory rheumatism at the ages of five, eleven, and eighteen years, of dyspnea on exertion during the previous three months, and during one month moderate swelling about the feet and ankles. Two or three recent attacks of fainting with dizziness and cardiac weakness had led her physician to advise immediate removal to a lower altitude.

On physical examination I found the patient rather enemic and poorly nourished, her weight being about 105 pounds. There was slight edema about the ankles and shin-bones. There was no cyanosis, and no dyspnea was perceptible at the time of examination. The lungs were negative. The heart was very considerably enlarged, the apex being 2 inches outside the mamillary line, and the right border 1½ inches to the right of the median line. Its action was regular, though somewhat exaggerated. At the apex was a marked thrill. Auscultation disclosed a diastolic blowing souffle at the base, heard loudest in the third space close to the left sternal margin, where it quite replaced the second sound. Over both the aortic and pulmonic valves the second sound was quite clear, and over the latter it was accentuated. At the apex there was a double souffle—one plainly systolic, blowing in quality, and replacing the first sound, and another also blowing in quality and occupying the latter half of diastole. It seemed that the latter was probably stenotic, although it lacked the usual rough quality of this murmur. The liver was slightly enlarged downward on percussion, but its edge was thin and not palpable. The urine was non-albuminous, and further examination of the abdominal organs was negative. The diagnosis was, therefore, chronic rheumatic endocarditis of both mitral and aortic orifices, mitral stenosis

and regurgitation, aortic regurgitation, and dilatation of both right and left heart with beginning failure of compensation.

Ten drops of tincture of digitalis three times daily was prescribed and careful directions were given as to exercise and diet. On October 22nd, sixteen days later, I was hastily summoned by the report that she was dangerously ill from sudden "heart failure." I learned that in the meantime she had felt better, gone back to Cripple Creek, had another spell there of heart weakness and fainting, returned immediately to Denver, and apparently continued to improve until this present attack which had followed immediately upon a walk of several blocks. I reached her at 8.30 P.M., about an hour after the attack began. She was sitting propped up in a chair, with head drooping and marked cyanosis of the lips and fingers, breathing with moderate difficulty, and constantly passing a large quantity of white frothy sputum. The pulse was very rapid—I should say 140—with irregularity, rather hard but empty. The edema of the feet noted at the first examination had disappeared. On listening to the heart, its action was found to be so tumultuous that the movements were hard to distinguish. The lungs were choked with coarse and fine moist râles throughout the lower two-thirds at the back, both sides, and the lower third in front. The rate of respirations was only about 30; but it was evident that there was quite a considerable degree of "air hunger," and the patient was continually complaining that she could not get her breath. One-fourth of a grain of strychnin had been given by another physician before my arrival, and I immediately injected 1-30 of a grain more. I gave, as soon as possible, about 7 grains of camphor hypodermically in the form of a ten-per-cent. solution in olive oil. Two drops of a one-per-cent. solution of nitroglycerin was administered, in the hope of easing the left heart. In spite of these measures the patient grew steadily worse. At 10 o'clock the cyanosis had increased, the breathing was more labored, and the complaints, "I can't breathe," "If I could only get my breath," were more constant and pitiful. The pulse had become more rapid, and râles could now be heard even in the upper part of both lungs. Cough was almost continuous, and the sputum, the quantity of which was enormous, was now stained with blood. The cerebrum also began to show signs of intoxication and the patient complained that the room looked dark and that her vision was indistinct. It was quite evident that the case was moving in the direction of a fatal termination.

It seemed to me, therefore, that the only possible means of relieving the pulmonary stasis was venesection. The left ventricle had evidently faltered in its task of compensating a double valvular lesion, and powerful cardiac stimulants had failed to impart sufficient vigor to affect a destruction of equilibrium. Oxygen would undoubtedly have given some temporary relief, but could have had no effect on the underlying mechanical condition. Active catharsis might have depleted in time, but here there was evidently no time to spare. The only possible recourse appeared to be the direct removal of venous blood, although the subject was already enemic, and far from the robust condition generally associated with the thought of venesection.

I asked Dr. J. N. Hall of this city to see the patient with me, requesting him to bring a lancet and bandage. Since his opinion accorded perfectly with my own as to the advisability of venesection I proceeded to overcome the objections of certain members of the family, who insisted that "it would be sure to kill her," and removed twelve ounces of blood from the right median cephalic. The result was remarkable and almost instantaneous. It is true, the first effect was a pronounced feeling of faintness, but this was soon overcome by the recumbent posture, and in a few moments the patient affirmed that she could breathe much easier. And indeed no such statement was necessary in order to assure us that there was, at least temporarily, a wonderful improvement. The cyanosis of the lips had nearly disappeared, the cough and abundant expectoration had ceased, the respiration was slower and less shallow, and the pulse, which was now softer and fuller, had fallen to 108. The heart had evidently been greatly relieved.

Venesection was performed at about 11 P.M. Soon afterward, in order to assist still further in maintaining the pulmonary depletion, I applied two large dry cups to the back. Fifteen minims of tincture of digitalis were also injected subcutaneously to guard against recurrence. At 1 A.M., although the patient was quite comfortable and breathing easily, 1-12 of a grain of morphin was injected with the thought that such a dose would possibly add to the increasing comfort and act, if at all, as an additional cardiac stimulant. By 2 A.M. improvement was even more marked; only a few râles were to be heard in front, and since all danger seemed to be past I left the patient for the night.

The subsequent history was uneventful. In thirty-six hours râles had wholly disappeared from the chest, and the patient, except for some weakness, was in every way as well as before the attack.

It may, perhaps, be of interest to note that immediately after venesection the only murmur to be heard was a rough, rumbling presystolic one, almost like a reduplication of the first sound. Later (on the following day) the systolic murmur had disappeared, and finally the aortic diastolic murmur was also not to be distinguished.

There are two reasons why the foregoing case seems to me worth reporting. In the first place such attacks of acute pulmonary edema are not at all common. While it is one of the most frequent things in practice to meet with an edema of the lungs, such edema is usually either an accompaniment of general anasarca and a mere terminal development; or it is partial, more subacute or chronic, and relatively unimportant. Here the edema might probably be termed *acutissimum;* it came on without warning, under fairly good compensation of the existing heart lesion, and within a couple of hours became so threatening as to make it evident that without relief the patient would rapidly succumb. Such cases are certainly rare, and yet exceedingly important because of the energetic treatment which they demand.

Again, the brilliant result of venesection in this case is not without interest, and may prove a stimulus to others in a like emergency. Fifty years ago it would have seemed ridiculous to report a case of simple venesection, but to-day it is a different matter. It is really not so easy to decide to bleed a person in the face of the strong sentiment against the procedure which exists in the minds of both laity and profession. A death after venesection is likely to arouse much comment, especially if the patient appears to be already weak and bloodless. In the present instance it certainly seemed a desperate remedy, and yet I am convinced that nothing else would have arrested a fatal result.

The indication for venesection in cases of pulmonary edema would seem to be its sudden and excessive development as a result of acute pulmonary congestion in a patient who has hitherto shown but moderate signs of failing compensation. Where it occurs in cases of general anasarca, toward the close of life, it is very questionable whether it is the edema which destroys life, or whether this is not rather due to a progressive cardiac insufficiency of which the edema is a mere terminal incident. At all events venesection is rarely indicated under such circumstances; no case has ever come under my observation where it was even considered. To feel justified in resorting to it, one must be confident that the edema is an accident, as it were, resulting from some sudden and unusual strain upon the heart, from which the latter is quite capable of rallying if only the extra burden be once removed. The good which it may then accomplish is certainly one of the most striking and beneficent results of therapy that the writer has ever seen.

MEDICAL PROGRESS.

Volvulus of the Stomach.—BERG (*Centralb. für Chir.*, September 3, 1898) describes two cases of twisting of the stomach upon its axis, the diagnosis resting not only upon the symptoms which were present, but being confirmed by operation and the course of the trouble during convalescence. In both instances operation was performed with entire success. From the character of the lesion the name volvulus of the stomach seems a suitable one.

Spasmodic Tumor of the Stomach.—SCHNITZLER (*Centralb. für Chir.*, September 3, 1898) found upon repeated examinations of the abdomen of a hysterical woman aged thirty-five years, a tumor in the pyloric region. The tumor was the size of a small apple, movable, though not moving much with respiration, and painful on pressure. It was not present at all examinations. Laparotomy was performed, and the stomach appeared normal, although the pyloric muscular apparatus was somewhat thickened. Suddenly under the eyes of the operators a tumor developed about 3.5 inches long and 2 inches wide, extending upward from the pylorus. This subsided in forty-five seconds, but reappeared some minutes later. A pyloroplasty was performed for the relief of the ulcer suspected to be present, upon the same principle that the sphincter of the anus is stretched for a fissure.

Puncture of the Transverse Colon in Typhoid Fever.—DALGLEISH (*Lancet*, October 1, 1898) mentions an instance in which ready action on the part of the physician undoubtedly saved the life of a young man suffering from typhoid fever. The case progressed rapidly, and on the seventh day tympanites displaced the heart and interfered with its action. The apex beat was well above and to the left of the nipple. The passage of a long tube up the rectum led to the evacuation of a quantity of offensive fluid, but the distention was not relieved. The transverse colon could be plainly seen through the abdominal walls. A trocar and cannula were, therefore, pushed into it, and gas escaped with a loud noise for two minutes. The temperature dropped from 104° to 100° F., the bowels became regular and stronger, delirium disappeared, and gas was thereafter passed from the anus. No untoward symptoms followed this radical procedure. Eight days later there was hemorrhage from the bowels, and the case throughout was a severe one, but the patient ultimately recovered.

Advantages of a Permanent Closure of the Rectum after Operations for Cancer.—KEEN (*Louisville Jour. of Surg. and Med.*, September, 1898) has come to the conclusion that after a resection of the rectum for cancer the patient is in a more comfortable condition if the lower end of the bowel is closed altogether, and the feces are allowed to escape through a permanent abdominal fistula. The sacral anus is unsatisfactory because it necessitates the wearing day and night of a napkin, and there is often beside more or less prolapse of the bowel, and frequently involuntary escape of fecal matter. Moreover, if an operation is done without a preliminary abdominal colostomy there is great danger of infection, because it is impossible thoroughly to cleanse the bowel and protect the wound. Keen, therefore, always precedes his resection by a Maydl's colostomy. Then the upper bowel can be thoroughly emptied and the lower one cleaned in a manner which would be impossible if such an opening had not been made. The rectum is then resected and permanently closed. The condition of the patient afterward is most satisfactory. He can wear a belt as tight as is necessary, both to prevent the escape of feces as well as to prevent prolapse, and the situation of the anus is such that its care can more readily be attended to by the patient himself than when it is in the sacral region.

Diagnosis of Pulmonary Tuberculosis in the Child.—MEUNIER (*La Presse Med.*, August 13, 1898) makes the diagnosis of pulmonary tuberculosis in the child by miscroscopic examination of swallowed sputa. He speaks of the different methods by which attempts have been made to obtain for examination the sputa of young children suspected of having pulmonary tuberculosis. As is well known, the young child does not spit, but swallows the discharges from the trachea and lungs. Two methods have been proposed to obtain this mucus for microscop-

ic examination. Kauffmann, by means of a sound and swabs, wipes out the back of the throat. Kossel, by examining the sediment of the fecal matter collected in the centrifuge has been able to stain and demonstrate the presence therein of tubercle bacilli. Meunier finds it far simpler and more satisfactory to pass a tube into the stomach and empty and wash out that organ. The swallowed sputa are readily recognized, and obtained for a microscopical examination. In fifteen cases in which this method of examination was carried out and subsequently confirmed by post-mortem examination, it was found that only in one instance did the microscope fail to reveal the presence of bacilli when pulmonary tuberculosis existed. This method of examination can be more successfully applied in advanced cases in which there is abundant sputum of a mucopurulent character.

A Word as to the Suture of Hairy Skin.—BOND (*Maryland Med. Jour.*, September 24, 1898) says that an oblique wound through skin in which hairs are growing is often prevented from uniting, even though approximately stitched. This is because of hairs which have been divided obliquely. As they continue to grow they are unable to find their openings in the superimposed flap, and therefore grow up between the upper and lower edges of the wound, causing irritation, and possibly stitch abscess. The treatment for such a wound is to open it, liberate the hairs, and cut off the projecting flap in order that the deeper hairs may have no overlying tissue to interrupt their growth. These facts will explain both the slow healing of wounds of hairy skin and the wide white scars which are so common in the scalp and face.

Diagnosis of Typhoid Fever by the Aid of the Microscope.—MACLEAN (*Maryland Med. Jour.*, September 24, 1898) has been greatly assisted in the diagnosis of cases of typhoid fever by microscopic examination of the blood. Almost all local inflammatory processes produce leucocytosis, while typhoid, if free from complications, does not do so. In two cases which appeared to be typhoid fever the examination of the blood showed no leucocytosis. Further developments proved that both of these patients were suffering from abscess of the liver. At other times the blood-count has served to distinguish appendicitis and typhoid. Late in the disease various complications, such as otitis media, perforation or abscess, will lessen the value of this symptom, but in the early stages the absence of leucocytosis is strong confirmation of a diagnosis of typhoid. The writer emphasizes the following points:

1. The absence of leucocytosis is strong evidence that an existing fever is typhoid, malarial fever being excluded by absence of the plasmodium.

2. If leucocytosis does occur in the course of an unmistakable case of typhoid it indicates some untoward complication.

3. Both feces and urine should be carefully disinfected throughout the course of the disease. Too often directions to this effect are omitted by attending physicians.

4. Widal's reaction is diagnostic in many cases in which, at the time, clinical findings are obscure.

5. The value of serum diagnosis, as well as other methods, must be determined by the practitioner who controls the patient upon whom the tests may be made.

THERAPEUTIC NOTES.

To Increase the Power of Trional.—HABERMANN (*Centralb. für Inn. Med.*, September 17, 1898) administers trional in carbonated water, which by reason of the carbon dioxid contained in it, dissolves the drug and conceals its taste. It also hastens its action so that the patients often fall asleep within ten minutes after drinking the half or the quarter of a 12-oz. bottle containing only 15 grains of the drug. With such a small dose the patient sleeps eight hours and awakes without feeling tired and without headache.

Poisoning by Lysol.—CRAMER (*Centralb. für Gynäkol.*, October 1, 1898) reports a case of fatal poisoning from the use of three pints of one-per-cent. solution of lysol as a uterine douche. Several cases of death following the ingestion of pure lysol have been reported, while in three instances its application upon skin wounds has resulted fatally, but so far as known this is the first fatal case from the use of a diluted solution of lysol. The uterine injection was made immediately after the birth of the placenta but was suddenly interrupted by the collapse of the patient. She recovered from the collapse, however, only to die ten days later with symptoms similar to those of carbolic-acid poisoning. Cramer reckoned that a quantity of lysol equal to 7 minims of the drug may have found entrance to the venous circulation. The value of uterine injections depends not so much upon the disinfecting power of the fluid used as it does upon the mechanical cleansing. Hence, the importance of having the antiseptic fluid as weak as possible in case irrigation is employed after childbirth. Indeed, for this purpose, many prefer normal salt solution to any disinfectant.

A New Method of Treatment of Inflammatory Pelvic Troubles.—PINCUS (*Zeit. für Geburt. u. Gynaek.*, vol. XXXIX, p. 13) gives the following rules for the treatment of inflammatory troubles of the pelvic organs, which are based upon a wide personal experience as well as the study of the literature of the subject:

1. The treatment of inflammatory and exudative processes in the parametrium, pelvic peritoneum, and tubes ought to be a non-operative one. Surgical measures are to be regarded as a last resort, except in the case of those who are unable to afford the time and money for a conservative treatment.

2. The object of treatment should be, surgically speaking, the attainment of perfect rest of all the organs of the pelvis.

3. This is only to be secured by: (*a*) increase of the abdominal blood-pressure; (*b*) assistance of the venous current in its return; (*c*) greater rapidity of the lymph stream, with the help of gravitation; (*d*) elevation of the organs of the pelvis, at least the affected parts being

lifted well out of the cavity of the pelvis; (*e*) the greatest possible immobilization of the affected organs.

4. To accomplish these ends the patient should be placed on an inclined plane, making an angle with the horizon of from 12° to 35°, and compression should be exerted upon the abdomen. By auto-transfusion the medulla and the heart are stimulated to greater endeavor. Respiratory gymnastics should be practised to increase to its limit the aspirating power of the respiration. The diet should be carefully looked after, and not only the strength but the weight of the patient be kept up, so that the normal fat around the pelvic organs may not be wanting.

5. Treatment on an inclined plane should be continuous, interrupted only in those cases such as puerperal ones, in which there is a uterine discharge, or in which douches have to be given, etc.

6. Compression is either direct or indirect. Direct pressure may be accomplished upon the abdominal wall or through the vagina. It is usually best to exert pressure in both ways at the same time. Vaginal pressure is in most cases no more than the immobilization of the pelvic organs. Abdominal pressure may be produced by an elastic bandage, rubber plaster, a bag of meal, or by moist potter's clay from two to ten pounds. Vaginal pressure may be produced by an air pessary, by a colpeurynter, or by tampons. All of these should be perfectly aseptic.

7. Pressure should be continuous or intermittent according to the nature of the case. In acute cases it should only be applied in conjunction with inclination of the body, and should be employed only so far as fever and pain are thereby reduced. In chronic cases pressure should be continuous, unless pain or fever manifests itself. Pelvic massage is of great assistance in such cases.

8. This method of treatment, combining compression with the force of gravity, is of great service in all affections in which there is hyperemia of the pelvic organs, or in which it is desirable to improve the position of the uterus, or to loosen adhesions, as well as in the troubles already mentioned. The most striking benefit is received in chronic cases of parametritis, pelvic peritonitis, and affections of the tubes. The length of treatment varies according to circumstances from a few days to several months. In chronic cases, whenever possible, the patients should be up and about. At night the inclined position should always be taken, as well as occasionally during the day, but at other times the effects of elastic bandages on the abdomen and vaginal distension are sufficient to achieve the end sought.

9. If in spite of treatment the exudate does not grow smaller—this may happen in puerperal parametritis—and even with a light fever there is loss of strength, there is not only pus present, but most probably a perforation as well, which must be treated by operation.

Intoxication Produced by the Administration of Felix Mas.—SIDLER-HUGUENIN (*Corres.-Blatt für Schweizer Aertze*, September 1, 1898) has collected 78 cases of intoxication produced by the administration of Felix mas. No fewer than 12 of these patients died and 33 suffered from permanent blindness. In 18 instances the trouble was bilateral, and in 15 unilateral. Five other patients lost permanently some of the acuteness of their vision. Six others lost their sight temporarily. The examination of the eyes of these patients showed the lesions of simple atrophy of the optic nerve. These figures are sufficient to convince any one of the danger attending the administration of large doses of this poisonous drug. It is doubtless true that many lighter cases of poisoning are not reported. The symptoms in such cases are nausea, weakness, stupor, ringing in the ears, headache, heaviness of the limbs, trembling, hiccoughs, jaundice, albuminuria, with hyalin casts and ischuria. Such symptoms pass away in a few hours or in a day or two. On account of the poisonous attributes of Felix mas attempts have been made to separate its active principles but so far with incomplete success. The extracts, in order to have the best effect must be absolutely fresh; it is also important that the roots from which the extract is made should have been freshly gathered. The administration of castor oil, either before or after this drug, is to be condemned, since it seems to increase its toxicity. Some saline should be given if a laxative is necessary. Special caution is necessary in the administration of Felix extract to anemic or ill-nourished individuals. The preceding treatment of these patients should be made as short as possible, and if the earlier doses of Felix mas produce symptoms of intoxication no more of the drug should be given. If severe symptoms of intoxication manifest themselves they should be treated by injections of ether and camphor.

Meat in Lithemia and Gout.—BAUM (*Phila. Polyclinic*, October 1, 1898), who has tested lithemic and gouty patients with various kinds of diet, finds that in order to secure definite results it is best to order a fixed course of food for a certain period, and to discontinue all medicines during the test. Animal food, excepting milk, will cause a deposit upon the teeth of gouty patients within half an hour after a meal. If a meat diet is persisted in, there results a listlessness and irritability of temper, and often, depression of spirits. There may be pain around numerous small joints, cramps in the muscles, soreness in the heels, neuralgic pains in the head, offensive breath, bleeding of the gums, fevered tongue, scanty, high-colored urine, drowsiness, lassitude, ringing in the ears, cold feet, irregular heart, etc., etc. If a full diet, or even a moderate diet of animal food is taken for several weeks or months a gouty patient will be sure to exhibit some or all of the above symptoms. If a diet is prescribed which furnishes a minimum of products to be excreted, an improved condition of health will soon manifest itself. No poisons are more rapid in their action than those produced within the body. Meat supplies material for the manufacture of poisons so that in severe cases milk is the only animal food which should be allowed. It will rarely produce discomfort. As a rule, white potatoes are not well tolerated. Many patients cannot eat tomatoes and rhubarb. Each patient must experiment until a diet of suitable vegetables is found. The secret of success in the treatment of these diseases is to lighten the labors of the weakened eliminating organs.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed *exclusively* to THE MEDICAL NEWS will after publication be liberally paid for (accounts being rendered quarterly), or 250 reprints will be furnished in place of other remuneration. When necessary to elucidate the text, illustrations will be engraved from drawings or photographs furnished by the author. Manuscripts should be typewritten.

Address the Editor: J. RIDDLE GOFFE, M.D.,
No. 111 FIFTH AVENUE (corner of 18th St.), NEW YORK.

Subscription Price, including postage in U. S. and Canada.

PER ANNUM IN ADVANCE	$4.00
SINGLE COPIES	.10
WITH THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, PER ANNUM	7.50

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

LEA BROTHERS & CO.,
No. 111 FIFTH AVENUE (corner of 18th St.), NEW YORK,
AND NOS. 706, 708 & 710 SANSOM ST., PHILADELPHIA.

SATURDAY, DECEMBER 3, 1898.

AN enterprising bureau of newspaper clippings in Germany has recently sent us marked copies of the newspapers published in German in which quotations from the MEDICAL NEWS have appeared during the past year. We have been not a little interested and gratified at the number of German papers by which we have been quoted, and think our readers may share some of our feeling of satisfaction in the matter. The list of papers includes the Berlin *Volk's Zeitung*, the *Berliner Fremdenblatt*, the *Berliner Zeitung*, the *Deutsche Tageszeitung*, the *Deutsche Wacht* of Berlin, the *Leipziger Neueste Nachrichten*, the *Dresdener Journal*, the *Magdeburgische Zeitung*, the *Kölnische Zeitung*, the *Stettiner Neueste Nachrichten*, the *Fränkischer Kurier* of Nüremburg, the *Chemnitzer Tageblatt und Anzeiger*, the *Neue Freie Presse* of Vienna, and the *National Zeitung* of Basel in Switzerland. The articles principally quoted are our letters from Cuba during the war, our foreign correspondence, and the reports of the proceedings of medical societies.

IT is officially announced that a six-day continuous bicycle race is to begin at Madison Square Garden, New York City, on December 5th. The New York consulate of the League of American Wheelmen, with the best interests of cycling at heart and a due regard for humanity in view, endeavored to have the Board of Aldermen of the city pass an ordinance forbidding it, but their efforts were in vain. New York is to be treated to another of those revolting exhibitions which have characterized six-day continuous cycling in past years. The daily papers will report in detail the mental hallucinations that the contestants are laboring under as the result of their persistent overexertion, and the morbidly curious will flock to gaze and wonder, and eventually be amused. The managers will reap their rewards from this morbid curiosity of the public, and though a few more physical wrecks will be added to the list, the offense to a right sense of humanity will be quickly forgotten. We had hoped we would be spared the exhibition this year but the city fathers doubtless have convincing reasons why the very commendable appeal of the representatives of what is best in cycling should go unheard. We reserve further comment till after the event.

THE following communication from Professor D. G. Brinton of the University of Pennsylvania recently to *Science* seems to need no comment beyond his own: "In the *Revue Scientifique* for April last Dr. Cesare Lombrosa, in an able discussion of the relative influence of heredity and environment, announced the conclusion that 'the influence of environment is potent enough to annihilate all ethnic traits.' "At the meeting of the German Anthropological Society, in August of this year, Professor Kollmann of Basel, in an address on the same subject, stated the dictum of science to be that 'the influence of heredity is far stronger than that of environment. The ethnic traits are immortal and persist, though the peoples who bear them may disappear from history.'

"These are two of the most eminent authorities among European anthropologists. As the traditional circus man said, 'You pays your money and you takes your choice.' "

RAILROAD EMPLOYEES AND FIRST AID TO THE INJURED.

THE value and the efficiency of the prompt application of aseptic dressings to wounds of every

character as employed during the recent conflict in Cuba has been shown with the conclusiveness of a demonstration. The ready inference is that in every large enterprise in which machinery is employed such a supply of aseptic dressings and bandages as will afford facilities for prompt aid in case of accident should be kept on hand. It must not be forgotten, however, that the success of the experiment in the army lay in the fact that every soldier was carefully instructed in the use of these appliances, and, therefore, employed them intelligently. It is not enough to have the material at hand, the knowledge of how to use it efficiently must also be supplied. In unskilled hands such things may do quite as much, perhaps even more, harm than good. Hence, we ask for the proper drilling of employees in their use.

In no department of civil life do these thoughts find such pertinent application as to the railroads of the country. Not only is there here a great army of employees in constant danger of more or less serious accident, but the great traveling public is equally concerned. The public has a right to demand, therefore, the most thorough system of human and mechanical safeguards against accident, and a thoroughly equipped and competent corps of men as well, to meet the accident emergencies when they arise. A conviction of the efficiency of this arrangement in the prevention of serious consequences from accidents as well as the saving of life should be sufficient to prompt the management of every railroad of the country to its immediate adoption. Every dictate of humanity, as well as financial interest, demands its enforcement.

A system of drilling railroad employees in the giving of first-aid has been adopted by certain of the English railroads, and is giving such good satisfaction that its acceptance by other roads is looked for in the near future. The benefits to be derived from this feature of employees' training are so patent that they need scarcely be insisted on. That at times life even would be saved there is no doubt. Then suffering would always be alleviated and certain complications of the after-course of the injury avoided by proper treatment at the beginning. Some one said during the late war that the prognosis of a wound not necessarily fatal because of its primary effect or its position was practically dependent on the first-dressing applied to it or its handling before it came into the surgeon's hands. The maxim is not so absolutely true of the lacerated wounds and crushing injuries of railroad accidents, but all of its application is not lost, and the first-handling, dressing, and moving of these patients remains of the greatest importance as regards the after-course of the injury. The length of time that a patient will be disabled depends to a great extent, in certain cases at least, on what is done, and especially what is *not done*, for him during the first hour or two after the accident. A meddlesome, though sympathetic humanity, sometimes makes sad mistakes in these cases. One of the most annoying items in the expense account of railroads is the damages for accidents and suffering and disability. There would seem to be in this expedient of training railroad employees in first-aid a most effective means of reducing this item of expenditure, and at the same time doing some very substantial good in the cause of humanity. Corporations are said to have no souls, but a distinguished American diagnostician has lent the weight of his authority as to the existence of a "pocket-book" nerve, and this much at least a corporation may be supposed to have. Under the circumstances, then, it may be confidently looked for that our own railroads will soon adopt this thoroughly practical and extremely humane method in the regular routine of railroad service.

Our railroad surgeons are, as a body, a select corps that contains some of our best practical surgeons, men whose experience in railroad accidents and whose interest in the patients that come into their hands under such circumstances, as well as their attention to the best interests of the companies, may be depended on to make the best use of the suggestion in this line, that comes to us so opportunely from our English railroad cousins.

ATYPICAL AMPUTATIONS OF THE FOOT.

WE call our readers' attention to the very interesting discussion of amputations of the foot held before the New York State Association of Railway Surgeons during its eighth annual meeting, the proceedings of which are briefly reported in this issue. Men of large surgical experience, which brings them especially in contact with crushing injuries of the foot, insist that for laboring men particularly, it is

the surgeon's plain duty to save every portion of tissue possible. There must be no such question as to which one of the classical amputations, Hays' or Lisfranc's, Mikulicz's, Symes', or Pirogoff's, seems to be indicated in a given case; every bit of tissue that can be saved must be saved, the foot treated as a whole and the bone sections made wherever sufficient soft tissue can be secured to cover the divided ends.

It is very probable that in the past the undue prominence given in text-books, and, may we add, in examination questions to these classical amputations of the foot have been a fruitful source of evil. The practical guiding principle now must be the same as that for the hand: save every bit of tissue possible, without regard to so-called types of amputations. When the art of constructing artificial limbs was less developed than it is at present there may have been some reason for selecting certain "points of election" in amputation. There is certainly no reason for such a proceeding on this score now.

One other bit of conservatism remains to be noted. It is that primary amputations are dropping into disfavor. It is hard to judge immediately after an accident how much tissue is likely to live. Where circulation seems to be absent at first, it is sometimes restored. The tendency of immediate amputation is to remove too much, so that the best surgeons advise delay until Nature makes clear how much tissue cannot live, and then remove only that. An important manifestation of this condition is the fact that surgeons do not longer consider it a reflection on their surgical skill to have to perform a second amputation. It is better, as Professor Wyeth says, to err on the side of conservatism in these days when anesthesia and aseptic surgery have deprived amputations of their terrors and dangers, and be compelled later to perform a second amputation, than to remove at first a single bit of tissue that might have made a laboring man's limb more useful to him.

THE "WOCHENSCHRIFT" IN A COMIC VEIN.

On the occasion of the sixty-fifth anniversary of the foundation of the Aerztlichen Vereins (the Physicians' Association of Munich), the *Münchener medicinische Wochenschrift* issued a special "Scherznummer," or comic number. The *British Medical Journal* remarks that despite the generally accepted dictum that the Germans like the Scots "jock wee deeficulty," the number contains some really good fooling, though perhaps at times over elaborate. Any one familiar with the genial, whole-souled, pleasant ways of the Bavarians and of the profession at Munich, recognizes how distinct they are from the stolider practical North Germans. It is identically the difference between the Scot and the South Briton.

As might be expected this second issue of a comic number contains some excellent witticisms on medical things generally and some telling bits of pointed satire on the present most prominent features of German medical life. Every bit of this issue from cover to cover, from the announcement that the present number is gotten out without the *slightest* assistance from the usual distinguished collaborators, to the final advertisement is given over to fun. Some of the ads are excellent; cards of Dr. "Inserter," who is off on a consultation and will not keep his office hours, or is soon to be back, and of Dr. ——, who never disappoints his patients by being absent, etc., etc., culminating in a large display ad. of Dr. Trommler of Wiesbaden who, from the palace of the Shah of Persia announces that he has been summoned to attend H. R. H. and cannot say when he will be back. The South Germans would not seek long to find a personal application in the ranks of the ethical "regulars" whom some of these and especially the last "cap" (*large caps*) would fit. A special institute for the treatment of the Dramatic Neuroses, in which stage-struck maidens are warranted to be cured of their sad affliction, is announced apropos of the multifarious special sanatariums for chronic disease. Dr. Schlaukopf ("Slyboots") announces a new remedy for premature baldness due to excessive professional business, an unusual disease.

The offer of an enterprising firm to supply "artificial assistants" who will not exhibit the excessive reflex irritability of the natural article, who will not criticize their chiefs, and who will not have and hold opinions different from them, will surely commend itself to some of our fashionable and over busy medical men. They are furnished in specifications to suit every requirement and are not expensive. A transparent (guaranteed not to hinder the view of onlookers) surgical assistant capable of thorough

sterilization that calls "sponge" and "pad" ten times a minute costs $300, twenty times a minute, $325. A medical assistant (ordinary) costs but $25, if supplied with a special mechanism for the staining of bacilli, results always positive, the cost is $50. A gynecological assistant guaranteed to vaginofixate *every* uterus is worth $2.25, to vesicifixate every uterus, $4.75. As there are very large quantities of these on hand they may be had cheaper in lots. An assistant that will "antefix" only when necessary cost $50, one that will never (!) antefix or employ any other treatment for retroflexion costs $100, but there is only one sample in the market. No American applications for this are yet announced.

A new antisyphilitic remedy, Iodosanin, is guaranteed to be such an inalterable combination of iodin with albumin that no iodism or *any other effect* is to be looked for from it.

Among the announcements of new books we notice "A Strampfer." The most frequent injuries of bicycling—those of the pedestrian. "The Voluntary Procreation of Twins," by Paolo Firlefanzi, Firenze, 1898, and "The Morbid Sensibility of the English, particularly in reference to the naval advancement of other nations," by John Grudget, London, 1898.

Among the original articles is one on "The Artificial Production of Asexual Reproduction in Man (Homo Sapiens)." Tolstoï having shown in the "Kreutzer Sonata" that the present method of reproduction of the human species is horrible and utterly unsympathetic to the cultured soul, it is to be abolished. The product to accomplish this purpose is a concentrated extract of certain lower organisms that multiply by division and is called Tolstoiidin. Some experimental success is announced with the new remedy *of course*. "A Triumph of Modern Surgery," the removal of the stomach of a German student troubled with unquenchable thirst and the substitution of a pig's, followed later by the implantation of calf's brains, is by a distinguished fellow countryman, Professor Swindel of Mississippi College. All this is innocent fun, clean and pleasing, and not only gives the lie to the general impression among us that the German is lacking in humor, but ranks with the best of humorous conceptions.

Dr. Carl Beck Resigns.—Dr. Carl Beck announces that he has resigned his professorship at the New York School of Clinical Medicine.

ECHOES AND NEWS.

Dr. Herman Biggs Appointed Visiting Physician.—Dr. Herman M. Biggs has been appointed Visiting Physician to St. Vincent's Hospital, New York, in place of Dr. Joseph O'Dwyer, deceased.

Bubonic Plague in Russia.—The Russian government has enforced stringent measures for the suppression of the invasion of bubonic plague, which was recently reported at Samarcand.. There is every reason to believe that the precautions taken will be effective.

Yellow Fever at Havana.—The report of the Marine Hospital Service for the week ending November 19th announces fifty cases of yellow fever, with six deaths. Nearly all the cases are in the military hospitals. No new cases have developed among Americans. Indications are that the disease will now continue to rapidly disappear.

Medical Calendars for 1899.—The Antikamnia Company is out with a calendar for the coming year from designs similar to the one issued a year ago. The artistic coloring is attractive, and prompts the suggestion that if the same amount of talent were expended in a direction productive of designs less revolting it would be more acceptable to the profession of the country.

Too Good a Man to Lose.—Donald Maclean, M.D., Major and Chief Surgeon of Division, on duty at the United States General Hospital, Fort Monroe, having expressed an inclination to resign and go back to his practice and his home in Detroit, has been very highly complimented upon the "excellent work performed by him at the hospital" and he is cordially invited to remain in the service. The doctor has the matter still under consideration.

Craig Colony Prize for Original Research in Epilepsy.—The President of the Board of Managers of Craig Colony offers a prize of $100 for the best contribution to the pathology and treatment of epilepsy, originality being the main condition. The prize is open to universal competition, but all manuscripts must be submitted in English. All papers will be passed upon by a committee to consist of three members of the New York Neurological Society, and the award will be made at the annual meeting of the Board of Managers of Craig Colony, October 10, 1899. Manuscripts should be sent to Dr. Frederick Peterson, 4 West Fiftieth street, New York City, on or before September 1, 1899.

Tachypodia, or "Hot Foot."—Péan of Paris was once called in the capacity of a physician to attend a duel. One of the adversaries was so cowardly that he ran away after the first shot, unhurt. The four seconds, the remaining combatant, and the doctor stood looking at each other with embarrassment and discomfiture, when Dr. Péan broke the silence by saying gravely, "I know the disease that has suddenly attacked this gentleman." And, taking out his pencil and paper, he drew up a report as follows:

"At the first shot Mr. X. was taken with a sudden attack of tachypodia that would not yield to treatment. The seconds, therefore, on consultation with the physician, stopped the duel."—*Press and Circular.*

The Harold Frederic Case Again.—Mrs. Mills, the Christian Scientist, who has been indicted for manslaughter in the Harold-Frederic case was on trial during the week. It is believed now that the charge against the woman Lyon, the member of Frederic's household, will be withdrawn. The evidence showed that the only treatment that Mrs. Mills ever pretended to furnish consisted in reading her book to herself! (there may be some consolation in this if it was the usual Christian-Science twaddle) in Mr. Frederic's room. Once she misquoted the Bible and Frederic made her get a copy of the Scriptures and turn to the passage in order to prove her mistake. We protest that the leaders of the new medicine should know their remedies better than to make errors in prescribing them.

Relief for Widows and Orphans of Medical Men.—The fifty-seventh annual statement of the New York Society for the Relief of Widows and Orphans of Medical Men has just been issued. From this it appears that the funds of the society now amount to $230,781.11, securely invested, and the income for 1897–'98 was $10,518.28. Under the present by-laws of the society the annuities allowed are: To the widow $400 a year, but for every ten dollars or multiple of ten of income an amount equal to fifty per cent. of said income shall be dededucted from the annuity. Each child entitled to relief is allowed $100 per annum, subject to the same conditions as a widow. During the past year the society has extended aid to seventeen widows and six children of deceased members. The members of the society now number 138. The initiation fee is $25, the annual dues $10.

The Insane of New York State.—The Empire State makes provision for a small army of insane, according to the annual report for the year 1897 of the Board of State Commissioners in Lunacy. The whole number of committed insane in the State, public and private, on September 30, 1897, was 21,683; in State hospitals, including the inmates of the Matteawan State Hospital (for insane criminals), 20,843; in licensed private institutions, 840. The report further shows the general receipts to be $4,603,623.57, as follows: Proceeds of State tax, $4,368,712.80; from private and other sources, $234,900.67. The disbursements for the year were $5,489,819.49; for salaries, etc., $3,893,175; for new buildings, $608,556.73; repairs, $596,635. The greatly increased expenditure is due to the Matteawan State Hospital coming into the system, the expenditures for the combined years of 1896 and 1897 being less than the income for those years.

New Mexico from an English Viewpoint.—The new *Medical Review of Reviews* for October has in its leading article the following observations regarding the climatic treatment of tuberculosis, and says of the crusade against consumption recently inaugurated in London, that it is essentially a step in the right direction. In America the problem has received much attention, and over six years ago a French commission of medico-scientists was sent on a tour of the world with the object of deciding upon the most favorable spot for the treatment of pulmonary diseases. Southern New Mexico was finally selected by the delegates of the Société Medicale as the most favorable site for a consumptive sanatorium, the combination of almost perpetual sunshine, warm winters, considerable elevation, and dry aseptic atmosphere found in the southern counties of New Mexico affording conditions more favorable than those of any other locality.

The New York State Pathological Laboratory.—The ninth annual report of the New York State Commission in Lunacy, just issued, contains a full report on the methods and principles underlying the pathological work of the State hospitals, in the central laboratory in New York City. According to the *Charities Review*, November, this report "should receive careful consideration, for it not only develops methods of investigation, but presents a new view of the pathology on insanity which by common admission is less perfectly understood than any form of disease afflicting the human race; and, if any hope of alleviating this curse is held out, in a better understanding of its nature and prevention, no possible means should be withheld, or no lack of encouragement, toward its thorough investigation." Dr. Van Gieson, the director of the institute, is clear and explicit in his demonstrations and deductions, and cannot well be misunderstood.

No Bubonic Plague in San Francisco.—It was reported by wire from San Francisco during the past week that a disease, said to be bubonic plague, had been discovered in Chinatown. The entire district in which it appeared was put under strict quarantine regulations, but later developments showed that the disease differs materially from the plague, and, therefore, the first alarm has subsided and the quarantine has been raised. On October 28th, the French bark "Duchesse Anne" arrived at San Francisco, seventy-four days from Hong Kong. The Captain had died August 20th and a sailor September 19th, under circumstances suggesting to the officers who brought the ship into port the presence of bubonic plague. Dr. Rosenau, of the Marine Hospital Service, now reports that there is no special reason to think that either death was caused by the plague. The vessel was disinfected throughout, the crew bathed, and their effects steamed or sterilized by formalin, and released from quarantine.

Scallops in Sewage Waters.—Fairhaven, Conn., has a large industry in shell-fish which is being injured by sewage pollution. So large have become the quantities of factory refuse and sewage that pour into the docks that pleasure boats no longer anchor at that point. When the New York Yacht Club gave this as a reason for omitting its annual visits, it was laughed at, but now the citizens appreciate that the yacht owners discovered a condition which is becoming serious. When the Vineyard steamers went out this summer there was a trail of stench in

their wake as they stirred the water with their paddles, which demonstrated how polluted the river is with filth. Business at the Fairhaven bath-houses has fallen off, for it is only at high tide, and often not then, that the water is sufficiently clear to tempt a bather. Scallops taken in the upper harbor have caused fever among those who have eaten them, and physicians have declared that the shell-fish which live in the mud on the shore are dangerous to eat on account of the sewage. Many are agreed that there are things more serious than high taxes, and a menace to the health of the community is not to be lightly regarded.

Medical Registration in Connecticut.—The Regular Examining Committee of the Connecticut Medical Society has held eight special examinations during the year 1898, the last one November 8th. Seventy-five applicants were examined, five of whom were for midwifery only, seventy for general practice. Of the seventy general practitioners thirty-nine were found qualified and twenty-one not qualified, and six were conditioned. Of the latter three were afterward reexamined and found qualified. The results of the last examination have not yet been reported to the State Board. One of the rejected midwives was also reexamined and passed. This committee and the two other official examining committees have held a conference and decided to apply to the State Board of Health to appoint the time and place for examinations only once in four months, namely, in March, July, and November; that all examinations shall be written in English; and that at least seventy-five per cent. of answers must be correct to enable a candidate to pass; but that "conditions" may be allowed, if there are not more than two branches under a marking of seventy-five, and the markings not less than fifty, with reexamination at the expiration of four months.

Meeting of the New York County Medical Society.—The President, Dr. S. D. Van der Poel, read his Inaugural Address on "Some Medical Aspects of Life Insurance." Dr. W. H. Thomson read a paper on "Cuban Malarial Fever." It will appear in full in our columns in a subsequent issue. Dr. Sturgis moved the appointment of a special committee of three to confer with similar committees from other medical bodies in the State for the purpose of taking such measures as were deemed necessary to secure legislation for the regulation of the abuse of medical charity at the dispensaries. Dr. Farr offered an amendment to refer the matter to the comitea minora. The amendment was carried. Dr. Valentine offered a motion directing that 2500 copies of the By-Laws of the Society be printed and distributed to the members with the notices of the next meeting. Dr. Philips moved the motion be laid on the table, because the By-Laws recently adopted must first be approved by the State Society, and there is the possibility of some of them not receiving that approval when the printed By-Laws would have to be replaced, and needless expense incurred. Some discussion followed. The motion to table the matter was lost and the original motion of Dr. Valentine passed. Regular meeting, November 28, 1898.

SPECIAL ARTICLES.

A REVIEW OF THE REPORT OF THE SURGEON-GENERAL OF THE UNITED STATES NAVY.

THE report of the Surgeon-General of the United States Navy for the year ending October 1, 1898, is an important one. Much that it contains has already appeared in our columns but the official form in which these facts are now presented lends renewed interest to them. It contains the medical records of naval warfare carried on by modern battle-ships, with the many interesting problems they involve. It will be read and referred with pride by Americans because it contains the record of how a magnificently organized service under the direction of American medical men was able to cope successfully with the untried problems in sanitation and hygiene that modern naval warfare had set them, and because the advances it chronicles in certain lines will doubtless prove the fruitful seed for still further improvement in naval medical matters, not alone for America but for the world.

The statement that the medical inspector of the North Atlantic Squadron is in a position to make is indeed worthy of note: "It is estimated from data at hand that the average daily loss of strength from disease, casualties in battle, and the ordinary injuries incident to ship-life was about 2.5 per cent. That such a result was obtained after long confinement on shipboard and sameness of diet, during a tropical summer, without awnings and with air-ports closed by battle-plates at night, must be regarded as remarkable." Quite as gratifying is the report of the surgeon of the marine battalion: "We had no deaths from disease or any seriously sick while on Cuban soil." It is noted just before that the rule "Drink no water, except distilled, until it has been boiled," was faithfully observed. We may manifestly be as proud of the medical features of the naval history of the Spanish War as we shall ever be of the gallant deeds of the navy in action.

Two special features of the report seem worthy of mention: the detailed account of the service rendered by the hospital ships, and the discussion of the inadequacy of hospital and surgical quarters on board the most recent men-of-war. The first constitutes the official data for the initial chapter on the history of hospital ships in warfare. One is tempted to wonder if the second feature mentioned, *viz.*, the criticism of the utter inadequacy of present arrangements for caring for the wounded during action, will have the desired effect upon naval architects and cause certain changes in plans that will remedy the defects so clearly pointed out.

A REVIEW OF THE REPORT OF THE SURGEON-GENERAL OF THE UNITED STATES ARMY.

THE WORK OF THE MEDICAL DEPARTMENT DURING THE SPANISH WAR.

UNDER the above title Surgeon-General Sternberg issues a summary of his report for the year ending June

30, 1898. Details are discussed that practically bring the report down to October 1, 1898, so that the document contains in brief the medical history of the military arm of the service during the war. We turn to it with certain feelings of misgiving, especially after having reviewed the report of the Surgeon-General of the Navy. A careful perusal of it shows, however, to our mind, that though less successful than the naval medical department in preserving the health of those under its care, the army medical department is not deserving of the blame that has been heaped upon it from certain quarters. Difficult problems were met with admirable skill, and as soon as proper organization could be effected, in what was necessarily at first a heterogeneous corps of men in new and untried conditions, good results were secured. The medical history of the Porto-Rican campaign, undertaken after proper organization and without the haste that characterized so much of the military management of the war, may be pointed to with pardonable pride as a notable chapter in the medical history of campaigning in hot climates.

The comparison that is inevitably suggested with the correspondingly naval department is manifestly unfair. The navy, even in time of peace, is much more nearly on a war footing than is the army. In fact, the main effort of Congress for years might seem to have been to keep the army as far from a war footing as possible, and the idea had been allowed to grow up that we would probably never again need a fighting army. "The very small proportion of medical officers," to quote the Surgeon-General, "having experience of a military character impaired the efficiency of the department at the outset, though many of the staff surgeons from civil life showed great aptitude for the service." It was not to be expected, however, that the new appointees should master the problems of an unfamiliar and difficult service at once. Many learned by erring, and error was costly, and when the experience had been gained the war was over.

It does not in the least disparage the magnificent work of the naval medical department to say that their splendid success in the matter of sanitation was due to training before the war under such circumstances as made the experience a counterpart of what fell to their lot in the war. This was not true, for the military medical men, living at frontier army posts or in garrison, seeing practically nothing of camp life, and that little with only small bodies of men. There were a few of the older men survivors of the Civil War, who had had camp experience with large bodies of men, but even that was not so useful with the modern ideas of hygiene and camp sanitation that the development of medicine in these last thirty-five years have introduced. The ideas gained from the annual eight to ten-days' camping of the State militia for drill were, as the event has proved, misleading in the extreme. The sanitary measures that served excellently for so short a time proved treacherous aids when the camps were to be occupied for months, and the trusted experience thus gained brought costly disappointment.

Despite the universal experience in the matter of infectious and intestinal diseases, where large numbers of men camp together, there was no proper realization of the dangers ahead except by a very few. It was impossible to impress the men with the necessity for the precautions so strenuously advised. Moreover, despite rigid medical examinations quite a number of men unsuitable for military duty found their way into the ranks. The reduction of the age of admission from twenty-one to eighteen years allowed the entrance into the army of a large number of unformed youths, of incomplete development, still attaining their growth, illy calculated to stand the hardships of camp life, and on whom it was difficult to impress the necessity for careful sanitary precautions. Added to this, unfortunately, was the fact that in certain cases camps were near cities, and inebriety and venereal disease came to add to the general unhealthiness, to lower resistive vitality even in the robust, and to seriously complicate the caring for the health of the troops.

So much in extenuation of the unfortunate results of camp life. A glance at the mortality statistics to October 1st shows that a great deal of exaggeration has been indulged in by a sensational daily press as to the actual death-rate. The death-rates for May and June, 46 and 70, were not in excess of those of the army in time of peace. In July the death-rate became somewhat higher than that of most well-cared for cities, 2.15 for the month, an annual death-rate of 25.80 per 1000 living. In August it became excessive, 4.08 for the month, and dropped under energetic sanitary measures to 2.45 for September. Statistics so discussed are notably untrustworthy. In one sense the comparison with city death-rate has no place here, since the death-rate was in selected cases of mostly young, strong, previously healthy men, and one is inclined to resent what looks like an attempt to gloss over actual losses. The total mortality of the army, however, from May to September inclusive, was 1715 deaths in an army of 167,168 men, scarcely more than one per cent., certainly not a high death-rate under the circumstances.

Three needs of the army medical service are brought out by the report: an increased medical corps which is formally demanded; an independent quartermaster service for the medical department, to obviate in the future the sad state of affairs that developed at some of the camps, and the lamentable conditions that prevailed at Santiago. Finally, there is the need of an efficient corps of trained nurses for field and hospital work.

One evil attendant upon our political system that undoubtedly had its effect in lowering the efficiency of the army medical service during the war does not, we think, receive due notice from the Surgeon-General. Political influence had unquestionably a large share in the appointment of certain medical men whose training and capabilities but illy fitted them for the positions they secured. This is a feature not liable to come into prominence for long years again and only brought out on this occasion because of the hurry of enlistment, but the public condemnation of it now should be so strong that at no future time will an administration dare to make political capital out of positions involving such serious responsibilities of life and health.

SANARELLI'S SERUM IN THE TREATMENT OF YELLOW FEVER.[1]

BY EUGENE WASDIN, M.D.,
SURGEON, U. S., M. H. S.

SIR:—Under your instructions of September 16, 1898, to proceed to New Orleans, La., and endeavor to obtain cases of yellow fever in which to use the serum, I called upon the authorities of the Charity Hospital on October 1st, and upon those in charge of Touro Infirmary in that city, and made known to them your earnest desire to have granted us the privilege of visiting cases of this disease in those institutions and of using the serum in those we thought suitable, this to be done only in consultation with the attending physician.

Professor Ernest Lewis, Vice-President of the Board of Regents of the Charity Hospital, after consultation with the Superintendent of the institution, informed me that it was thought best to refuse your request on the ground that a test of the same serum, presented to the institution by Professor Sanarelli, was then in process, and that the limited number of cases in hospital scarcely furnished material for this test.

The authorities at the Tuoro Infirmary, especially Dr. Loeber. promised every facility for the use of the serum, manifesting a lively interest in the subject. At the same time they informed me that a definitely marked case of yellow fever was very rare in their hospital; that the prevailing type was so poorly marked, so slightly developed, that often it was found necessary to rely upon the fact of the presence of the disease in the community for a diagnosis. All such cases were treated very tentatively, scarcely any medicine being demanded; and in these it was thought there could be no definite results gained from serum exhibition, since they invariably recovered. Such were the cases then on hand. But I was promised instant notification of any admission of a serious type, and preparations were made to respond to such calls.

Consultation with Surgeon Carter, senior surgeon at New Orleans, on October 8th, no suitable cases having been admitted to the Touro Infirmary, decided me to seek at Wilson, La., then generally infected, cases in which to test the prophylactic influence of the serum, and I proceeded there on that date. In this village of some 600 people I found the majority of the population sick or convalescent from a very mild type of fever, so much so that there seemed but little evidence of alarm. Through the courtesy of Acting Assistant Surgeon Bland, U. S. M. H. S., I saw a number of these cases, and he and other local physicians soon acquainted the people with the object of my visit. There was evidence of an indisposition to be "experimented" upon and many declined "the South-American treatment." Of those who had been exposed, and who would probably develop the disease, there were three or four who expressed a disposition to submit to the prophylaxis, but they invariably asked for a guarantee, and when this could not be given they hesitated between the unknown remedy and the light type of the disease.

However, two cases of tolerably well-developed yellow fever were found willing to receive the serum treatment, and these are detailed below. In the second case the use of the serum was followed by such annoying urticarious erythema, especially after the second injection, that the apprehensions of the family were aroused, and the fact of the new treatment having produced symptoms not seen in any other cases, and of so serious an appearance, immediately became the subject of general comment, and I quickly found the serum relieved of all sympathy, and invested with unknown possibilities for harm. I could get no consent to its prophylactic use.

At this time advices from Surgeon Carter directed me to Baton Rouge, La., where fever was then very rapidly spreading, and by invitation of Dr. C. McRea, I visited that city on October 12th. meeting and discussing with a large number of the physicians the probability of being able to use the serum. There was an expression of the liveliest interest in the subject and a disposition to render me aid, but a general conviction that they were scarcely warranted in advising the use of the serum in view of the very simple nature of the prevailing disease. In those cases developing more serious symptoms it was not deemed best to rely upon the serum. Hoping that cases might have occurred in the Touro Infirmary at New Orleans I returned to that city, and although there had been and were none suitable in that institution, I had the opportunity to see one at the United States Marine Hospital under the care of Dr. Faget. This is detailed below:

CASE I.—Robert Anderson; aged fifty years; a vigorous man, was taken sick at 10 P.M., October 8, 1898, with intense pain in back and limbs and a severe rigor, followed by high fever. When seen at 4 P.M. of the 9th, in consultation with Dr. Bland, the typical facies, pains, and commencing icterus left no doubt that he had succumbed to the infection to which he had been freely exposed. Thus far only a mild mercurial had been prescribed, and with his consent the antiamarylic serum was used. At 6.15 P.M., 10 c. c. of serum were injected into the connective tissues of the loin, pulse 84, temperature 101.6° F.; much congestion of vessels of the skin of the face. Temperature to be taken every two hours as nearly as practicable.

At 9 P.M., temperature 103.2°, pulse 86, more marked flushing of the face and some sweating; at 11 P.M., temperature 101.8°, pulse 84, semi-delirious and perspiring very freely, urine free; at 1 A.M., October 10th, temperature 101.4°, pulse 81, sleeping; at 3 A.M., temperature 101.1°, pulse 78, quiet; at 6 A.M., temperature 100.5°, pulse, 76, urine free; at 8 A.M., temperature 100°, pulse 66, urine free; at 9 A.M., 10 c. c. of serum were injected into the connective tissue of loin; at 10 A.M., temperature 100.6°, pulse 70, congestion of face; at 3.40 P.M., temperature 100.9°, pulse 78, sweating profusely; at 5.45 P.M., temperature 101.3°, pulse 78, urine free; at 7 P.M., temperature 101.4°, pulse

[1] Extract from report to the Supervising Surgeon-General, United States Marine-Hospital Service of tests made in Louisiana in the use of Professor Sanarelli's *serum antiamarylic* as a curative agent in yellow fever.

78; at 9.30 P.M., temperature 101.3°, pulse 74, restless; at 11 P.M., temperature 101.3°, pulse 72, slept one and one-half hours; at 1 A.M., October 11th, temperature 100.9°, pulse 74, urine free; at 3 A.M., temperature 100.9°, pulse 73, sleeping; at 5.20 A.M., temperature 101.4°, pulse 75, feeling weak; at 7.10 A.M., temperature 100°, pulse 70; at 9 A.M., temperature 99.8°, pulse 68, injected serum 8 c. c.; at 7 P.M., temperature 101.1°, pulse 78, urine free; at 10.15 P.M., temperature 100.7°, pulse 76, refused nourishment; at 3 A.M., October 12th, temperature 100.5°, pulse 76; at 6 A.M., temperature 100.5°, pulse 72, slept well; at 8 A.M., temperature 100°, pulse 75, urine free; at 5 P.M., temperature 100.4°, pulse 70; at 9 P.M., temperature 99.8°, pulse 68, bowels free; at 1 A.M., October 13th, temperature 99.3°, pulse 68, urine free; at 6 A.M., temperature 98.9°, pulse 62, takes food; at 6 P.M., temperature 100.1°, pulse 62, well; at 7 A.M., October 14th, temperature 98.6°, pulse 64; at 6 P.M., temperature 98.6°, pulse 68, discharged.

CASE II.—Fred. A., aged nineteen; a healthy young man, son of preceding patient, and much exposed to the infection, was taken sick at 6 P. M. of October 9, 1898, with a severe chill; pain in back and limbs, intense headache and nausea. He received a mustard bath and a mercurial with phenacetin. Temperature ranged from 101.3° to 103.1°, pulse 115.

At 9 A.M., 10th, he was given 12 c. c. of serum under the skin; temperature 102.7°, pulse 110; at 10 A.M., temperature 103.2°, pulse 110, and there was marked congestion of face, lips, ears, and body; at 12 M., temperature 103.2°, pulse 110; at 3:40 P.M., temperature 103.2°, pulse 110; at 6 P.M., temperature 102.5°, pulse 114, perspiring; at 8 P.M., temperature 102.2°, pulse 96; at 11 P.M., temperature 102°, pulse 98, slept well; at 1 A.M. October 11th, temperature 101.6°, pulse 96; at 3 A.M., temperature 101.3°, pulse 88; at 5 A.M., temperature 102°, pulse 98.

Complains of much dizziness; at 8.30 A.M. gave another 12 c. c. of serum under the skin, temperature 102.2° pulse 100; at 9.30, temperature 102.7°, pulse 100; at this hour the congestion of the face was extreme, and there was marked erythema; at 12 M., temperature 103.1°, pulse 105, perspiring and ptyalism; at 4.30 we were hastily summoned and found the patient suffering extremely from the urticarious rash, face puffed and congested, temperature 40°, pulse 110, urine abundant, copious saliva; at 6 P.M., temperature 103.2°, pulse 110, phenacetin given; at 8 P.M., temperature 101.8°, pulse 102, nausea; at 10 P.M., temperature 102.2°, pulse 104, and vomiting; at 12 M., temperature 103.7°, pulse 110, rash disappearing; at 2 A.M., October 12th, temperature 102.2°, pulse 105, urine scant; at 4.30 A.M., temperature 102.4°, pulse 105, slept well; at 6 A.M., temperature 102.4°, pulse 110; at 9 A.M., temperature 102.4°, pulse 97, perspiring; at 11 A.M., temperature, 102.5°, pulse 110; at 1.30 P.M., temperature 102°, pulse 106; at 5.30 P.M., temperature 102.8°, pulse 90, urine scant; at 7 P.M., temperature 102.6°, pulse 98; at 9 P.M., temperature 102.8°, pulse 98; at 12.30 A.M., October 13th, temperature 100.8°, pulse 88; at 4 A.M., temperature 100.2°, pulse 81, slept well; at 6 A.M., temperature 100.4, pulse 86; at 8 A.M., temperature 101.2°, pulse 83; at 10 A.M., temperature 101.6°, pulse 82; at 12 M., temperature 101.6°, pulse 85; at 2.30 P.M., temperature 101.6°, pulse 82; at 6 P.M., temperature 101.5°, pulse 83; at 8 P.M., temperature 101°, pulse 82, nauseated; at 12 M., temperature 100.2°, pulse 78; at 4.30 A.M., October 14th, temperature 99.6°, pulse 77; at 7 A.M., temperature 99.3°, pulse 76; at 9 A.M., temperature 99.2°, pulse 77; at 6 P.M., temperature 99.8°, pulse 80; at 10 P.M., October 15th, temperature 98.6°, pulse 78, discharged.

CASE III.—A. B., seaman, about thirty-five years of age, was admitted to the isolation ward at the United States Marine Hospital at New Orleans, October 13, 1898, and when seen in consultation with Dr. Faget was moribund from almost fatal suppression of urine. He was unconscious; there was hiccough and jactitation, small weak pulse, devoid of tone. In the hope that the serum would produce a renewal of the suppressed renal function, he was given 20 c. c. of serum under the skin, and although there was noticed a slight reaction in temperature from the subnormal, the kidneys did not react, and he died of a uremic seizure twelve hours after the administration.

One word as to the possibilities of this serum as outlined by Professor Sanarelli; because of its not being an antitoxin it does not tend to overcome the toxins of yellow fever produced in the system, and depends for its curative and prophylactic properties upon its germicidal influence. Hence, it is argued by Professor Sanarelli that its use will be absolutely negative in cases in which an amount of toxin has been produced sufficient to destroy life. These cases he does not attempt to treat, passing them by as out of the pale of serum influence. To those who have witnessed the successful struggle of many apparently beyond prognostic hope, there will at once arise the question of properly determining in such cases the fatal degree of intoxication which exists; therefore Professor Sanarelli advises and insists upon the early use of the serum, and thus the destruction of the organism before it has elaborated the fatal proportion of its toxin; such an exhibition of the serum invites the criticism that the mortality-rate must be that of selected cases, and, therefore, of diminished statistical value; and in an epidemic of mild type, such as the recrudescence of this fall in Louisiana, it would be contraindicated.

As to its influence in Case I. there was no doubt a very prompt reaction evidenced by the rise of temperature and pulse, and the great congestion of the face and skin of body. This was followed by a cessation of all pain in a few hours, and a fall of pulse and temperature to a point lower than before the administration. The second and third injections showed less marked reaction. The exhibition of the serum produced a free flow of non-albuminous urine, some ptyalism, and free perspiration. I am free to confess that the man would have done equally well with any ordinary medication.

In Case II. I am satisfied that the boy would have done as well without any medication. His mental and physical condition were not improved by its use. The

influence of the serum upon the vasoconstrictors was very pronounced, and caused mental and physical suffering. At first the urine was quite free, and always non-albuminous, but on the second day became more scant, yet the skin acted very freely. The rash was very general on trunk and limbs. The face, eyelids, and ears were swollen, puffed, and bluish in color, with slightly raised patches which resembled urticaria, the general surface being erythematous with scattered and intensely itchy plaques. The reaction in this case was excessive, the temperature rising to 104° F. The family requested us to desist from this treatment, and I did not object since the pulse was intermittent and dicrotic. As to the doses in these cases, I had never observed the action of the serum, and therefore refrained from the exhibition of the full dose directed by Professor Sanarelli, that of 20 c.c., and feel satisfied that the latter dose would have caused much alarm, and probably harm, in the second case reported. I regret that I have not been able to accomplish your purpose to have a full test made of this serum, but I realize that it was more necessary to arrive at a just conclusion of its merits, based on correct data, than to merely use it on uncertain cases. A more thorough test will be made at the earliest opportunity.

CORRESPONDENCE.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

THANKSGIVING WEEK AND DONATIONS TO HOSPITALS—THE CHARITY BALL—BANTI'S DISEASE—TREATMENT OF APPENDICITIS—ERYTHROMELALGIA—THE NUMBER OF SOLDIERS TREATED IN PHILADELPHIA—PERSONAL NOTES—HEALTH STATISTICS.

PHILADELPHIA, November 29, 1898.

WE seem to have had nothing but holidays lately, the Peace Jubilee celebration being scarcely over before Election and then Thanksgiving Day made another break in the regular routine of work.

Whether there is a small epidemic of a mild type of influenza or whatever may be the trouble, the peculiarly disagreeable weather of the last month has undoubtedly contributed to the vast amount of "colds" and so-called "grippe" cases which are now so prevalent here. The newspapers commented on the foolhardiness of some 20,000 people who braved the storm of Thanksgiving Day to sit two or three hours on wet, uncovered seats to witness the foot-ball game, and ventured the opinion that an appreciable increase in the amount of pneumonia, etc., would surely follow, a prediction which has been speedily verified.

Thanksgiving week was selected by many of the hospitals as donation days for receiving funds, clothing, and groceries to aid them in carrying on the large amount of charitable work in which they are engaged, Many of the smaller institutions depend almost entirely on such donations, for it seems to be a puzzling, but none the less true, fact that the smaller the institution, the greater the comparative amount of work done and yet the fewer bequests. Among Thanksgiving gifts was that of Mrs. Rebecca E. Shoemaker, who gave $5000 in five-per-cent. bonds to the Methodist Episcopal Hospital for the endowment of a free bed in honor of her mother, Mrs. Mary B. Clark. John B. Roach, the shipbuilder, gave the Chester Hospital a complete ambulance equipment, including the horse, harness, and ambulance. At the German Hospital more than $7000 was received, besides a large amount of groceries and clothing, and the Jefferson Maternity was the recipient of $500 and many gifts of food and clothing.

On January 23d the Annual Charity Ball is to be given, at which a large amount of money will probably be raised, which will be divided between the Pennsylvania Society to Protect Children from Cruelty, St. Chistopher's Hospital for Children, the Sanitarium Association of Philadelphia, and the Childrens' Department of the University Hospital. Among the members of the executive committee are the following physicians: Drs. Edward P. Davis, Hobart A. Hare, Barton C. Hirst, William Barton Hopkins, and John B. Shober.

At the College of Physicians last week, Dr. Henry Morris presented an interesting case of Banti's disease, which had occurred in a man aged twenty-one years. While a differential count of the blood showed practically no changes in the normal proportion, a numerical count of the erythrocytes showed a decrease to 1,400,000 with a percentage of hemoglobin of only twenty-seven. The spleen was enormously increased in size, the liver small, the urine normal except for an excess of urates, and there was no change in the lymphatics or in other organs. Dr. Hare said that the man had previously been under his care and that the blood then showed an increase in the number of lymphocytes and had a tendency to change, finally, however, assuming the appearance of pernicious anemia. Dr. Ashton, who had made the blood examinations, said that the blood had shown poikilocytes, normoblasts, megaloblasts, nucleated red cells, and other typical characteristics of pernicious anemia toward the last. Further discussion, which followed, served to bring out the difference of opinion held as to the classification of anemias and the unsatisfactory and inaccurate division.

Dr. H. B. Allyn outlined the "Medical Treatment of Appendicitis," in which he urged abstinence from food for twenty-four to forty-eight hours, gentle purging, and operative interference at the end of twenty-four hours if there is no improvement. He too, in common with most practitioners, advises against the use of opium, believing that it masks the symptoms, and only uses codein to take the edge off the pain when it is very severe.

Dr. S. Weir Mitchell and Dr. William G. Spiller reported an interesting case of erythromelalgia, only one other case having been reported with pathological changes since 1872, when the disease was first described. The signs of the disease were confined to the great toe, and upon amputation the nerves were found degenerated. Arteriosclerosis was present, and the bones of the toe were apparently enlarged.

The Hospital Committee of the National Relief Commission held a meeting last week at which representatives

of the various hospitals and Major D. C. Peyton, representing the Government, were present. It was determined that payment shall be made at the rate of $1 a day for each soldier treated, the Government settling the bills on that basis, and a vote of thanks was passed for the courteous treatment given to the hospitals by the Department as well as for the courtesy and kindness of Major Peyton. A report which has been prepared shows that 2860 soldiers were treated in this city up to November 1st, while the present number is about 3500, and the total amount due the hospitals is between $150,000 and $175,000. Pennsylvania, as a whole, has cared for about 5000 soldiers in her hospitals, of which about 100 have died, a mortality of 2 per cent.

Dr. George Lessmann, who was wounded at Santiago, is now ill with typhoid fever at the Lafayette Hotel. He served on the hospital-ship "Relief" and later in the division hospital at Ponce.

Dr. William H. Bell, assistant surgeon, U. S. Navy, has been ordered to Washington from the Naval Hospital on Gray's Ferry Road, Philadelphia.

J. J. Rosengarten, one of the trustees of the University of Pennsylvania, has presented an oil portrait of the late Dr. Pepper to the University Library, where it will be placed in the Pepper alcove.

Dr. A. O. J. Kelly has resigned the chair of adjunct-professor of pathology at the Philadelphia Polyclinic. No successor will be appointed, as it has been determined to abolish this chair.

The total number of deaths occurring in Philadelphia for the week ending November 26th, as reported at the Health Office, was 449, of which 121 occurred in children under five years of age. The number of new cases of contagious diseases was 247, reported as follows: Diphtheria, 129 cases, with 33 deaths; scarlet fever, 28 cases, with 1 death; typhoid fever, 90 cases, with 10 deaths.

MEDICAL MATTERS IN CINCINNATI.

[Special Correspondence of the MEDICAL NEWS.]

THE NEED OF A REFERENCE LIBRARY AT THE ACADEMY OF MEDICINE—PROSECUTIONS OF QUACKS—CINCINNATI HOSPITAL AFFAIRS.

CINCINNATI, November 28, 1898.

THE question of the erection of a fire-proof building for the exclusive use of the Academy of Medicine and for the formation of a library is one that periodically engages the attention of the profession in Cincinnati. The interest in the subject, however, has been spasmodic for the most part and productive of no results aside from the collection of a small building fund. The necessity and advantages of such a central club-house and library for the medical profession needs no argument; but in Cincinnati there seems to be an especial reason in our present library facilities for such centralization. In the first place the Academy of Medicine has been the recipient of numerous valuable library bequests, for the care of which it has no facilities; and secondly, our advantages in the direction of a reference library are very inferior. The Cincinnati Hospital library is large and of great value, but the hours during which it is open are so arranged that the busy doctor can rarely consult it without great inconvenience, a condition most unfavorable to scientific work. Furthermore, this library is peculiarly liable to destruction by fire, both because of its location in a general hospital, and of the presence of a large carriage and wheel factory not fifty feet distant. The City Library likewise contains a valuable collection of medical works which are also inaccessible in many ways. Should the Academy of Medicine construct a modern fire-proof building it would be possible to concentrate these valuable collections into a magnificent library that would be a credit to this great medical center. Many private libraries would certainly be donated to the Academy at once and others would be deposited for safe keeping, until the profession of Cincinnati would have reference facilities second to those of no other city.

The epidemic of smallpox which has been prevailing in Loveland, Ohio, is now under control after several weeks of rigid board-of-health regulations. The cases have all been mild, and have presented many difficulties in diagnosis, a confusion with chicken-pox being the chief feature. The epidemic nature of the form of coryza that has been prevailing for the past few weeks in this city cannot escape notice, and a bacterial origin seems to be its only explanation.

The meeting of the Research Society on November 10th was of unusual interest in the abundance of material which was presented. Dr. Langdon demonstrated a specimen of interpeduncular tumor of a confusing histologic structure. Dr. Rowe presented histologic specimens of the appendix vermiformis, gastric mucosa, and of cartilage, and Dr. Freiberg specimens of carcinoma of the bladder, sarcoma of the hard palate, and carcinomatous tissue taken at random in closing the wound after amputation of the breast.

The cases of illegal practice of medicine by non-registered physicians, as investigated and brought to trial by the State Board of Registration, will be heard in the courts during the second week in December. The prosecution of Dr. Campbell of the Fairmount Sanitarium and his followers in vitapathy will make up a goodly number of these cases. Certain female abortionists of the city will probably also be convicted. Recent evidence has been gained against Dr. France, the quack on "weakness in men," and against the "osteopathic" school in Toledo. Mrs. Harriet Evans, the Christian-Science healer, is under arrest both by the city authorities and the State Board of Registration, for the death of a certain McDonald, who died recently while under her care.

At a special meeting of the Cincinnati Hospital trustees, held on November 17th, the present medical staff of the institution was re-elected for another year, with the exception of the officers connected with the department of dentistry. In this department Dr. H. A. Smith will be succeeded by Dr. H. C. Matlack. The change was made because of the resignation of the former. Prior to the election the board discussed at length the present needs of the hospital. The necessity of an isolation ward, which has been apparent to the board for years, and which is no nearer being realized than it was when the subject was

first introduced, was gone over, as was that of the nurses' home and the needed additions to the branch hospital. A year ago plans were drawn for important additions to the hospital, and the board sent a committee to confer with the Legislature and ask for an appropriation to make the improvements, but the suggestion was turned down. The fact remains that these additions are necessary for the protection of the public, and they engross the attention of the board as deeply as ever. It was decided to sell the old surgical instruments now in use in the hospital amphitheater and to purchase new ones.

On November 30th, Dr. Horace J. Whitacre will begin a series of lectures on "The History of Medicine," at the Medical College of Ohio, which will be open to the profession. They will be profusely illustrated by lantern-slides.

MEDICAL MATTERS IN CHICAGO.

ACCESSIBILITY OF MEDICAL LITERATURE—DIAGNOSIS OF CHRONIC DIFFUSE PERITONITIS—TRANSPLANTATION OF THE SKIN—DR. NICHOLAS SENN'S EXPERIENCE IN SURGICAL DISEASES OF THE SPANISH-AMERICAN WAR—ENTERIC DISEASES OF ARMY CAMPS IN RELATION TO LIFE INSURANCE—EPIDEMIC CEREBROSPINAL MENINGITIS IN CHICAGO.

AT a meeting of the Chicago Medical Society, held November 9th, DR. EDWARD F. WELLS read a paper on "The Accessibility of Medical Literature." He said the extent of the medical literature of the world is known to but few; the volume of that which is being currently produced is appalling to the librarian; the inaccessibility of much of it is painfully evident to the practising physician. It is beyond the financial ability of the last-named individually to procure and care for it; it is a physical impossibility for him to read any but a very small fraction of it; even the titles he cannot compass. Nevertheless, it is the active medical practitioner for whom the greater portion of this printed matter has been prepared and to whom it is a real necessity. Public medical librarians have more than once complained that the vast stores of medical records which they have accumulated, and maintain at great expense, are not made use of to the extent which their importance would seem to demand and wonder why. The conditions under which the practising physician labors confine him closely to his residence or office; here he may have ample time for reading, but the time necessarily occupied in consulting a volume of the library, probably a long distance away, can only be spared at great inconvenience or actual loss. Under these circumstances the great majority of would-be students, after a few trials, adjudge the plan an impracticable one for them and attempt to meet their necessities in other ways. There are various methods, and thoroughly practicable ones, too, by which medical literature may be made more accessible, namely, the Denver plan of mutually accessible private libraries, journal, and new-book clubs; the combined circulating and reference public library. He believes the scope and usefulness of a public medical library may be extended by allowing the books to be removed, for a short time, from the library building. The physician desiring to use the library in this manner should be required to make formal application for the privilege. By this plan, properly elaborated as to detail, every physician's office may, with proper restrictions, be made practically a branch of the reading-room of the library.

At a meeting of the Chicago Academy of Medicine, held November 11th, DR. FRANK X. WALLS read a paper on "Diagnosis of Chronic Diffuse Peritonitis," in which he said that much discussion has arisen as to the existence of a simple, non-tubercular, exudative peritonitis, though cases have been described as occurring more frequently in children by Strümpell, Henoch, Baginsky, Filatoff, and others. There is no reason *a priori* why a chronic, simple inflammation of the peritoneum should be denied, even though the condition is admitted to be infrequent. The disease develops insidiously, often after a history of trauma or exposure. Pain and abdominal distention are the most prominent symptoms, directing attention to the peritoneum. The differential diagnosis should exclude tubercular or cancerous peritonitis and ascites. Osler and Baginsky have reported each a case of chronic peritonitis in which tubercle bacilli were demonstrated in the lesions during the early history of the disease, but later, when the case came to autopsy, careful search for bacilli or characteristic tubercular processes by competent pathologists was negative. The deduction is warranted that the absence of bacilli or tubercles in a chronic peritonitis is no indication that the morbid condition was not initiated by the bacillus of tuberculosis, and also that autopsical negative findings are quite consistent with a previous tubercular infection. He reported an interesting case of the disease illustrating the sign of Thomayer.

At the same meeting Dr. L. Loeb read a paper on "Transplantation of the Skin and the Origin of Pigment of the Skin." Experiments were made on the ears of guinea-pigs. White skin was put on a wound in black skin, and black skin on a wound in white skin. The experiments prove that the pigment of the black skin is not carried into the epithelium through cells from the connective tissue, but that it has its origin in the metabolic changes of the epithelial cells alone.

At a joint meeting of the Chicago Medical Examiners' Association and the Chicago Medical Society, held November 16, 1898, Dr. Nicholas Senn spoke on the "Surgical Diseases of the Late Spanish-American War," with a view of estimating the war risk of life-insurance companies. He said that the late war had been characterized by decisiveness and by intense patriotism on the part of the troops; while he had reason to believe that the opposite mental conditions prevailed in the Spanish camps. The American troops had to deal with an impoverished, half-starved, discouraged enemy, which he thinks accounted largely for the easy victories and the short duration of the war. He attributes the repeated victories on land and sea more to the soldiers than to any special military genius displayed by any of the commanders. The loss of life on the battle-field, or as the immediate or remote effects of wounds, did not exceed 400. The loss in battle in Cuba was 267. A number of the most seri-

ously wounded have died since. In Porto Rico, where there were four skirmishes, the number killed did not exceed 20, and the number of wounded was not about 40. The Spaniards were armed with Mauser rifles exclusively. He had abundant opportunity to compare the injuries inflicted with the Krag-Jörgensen rifle and the Mauser rifle, and the wounds differed very little. If any, the Mauser rifle was a more humane one, owing to the smaller caliber of the missile. The stopping power of these guns has been overestimated as every hunter of large experience knows. In examining from 1200 to 1300 of the wounded he was astonished at the limited zone of contusion of the soft parts, which explains very satisfactorily the readiness with which these wounds healed, provided no infection occurred. There is a zone of comminution from both weapons at a range of about 500 yards. He found in two cases among the Spanish prisoners shot with the Krag-Jörgensen rifle, gunshot wounds of the femur at the junction of the lower with the middle third; in both instances infection had occurred. The patients suffered from progressive sepsis; amputation was indicated and promptly performed in a most primitive way, outside of the Spanish column, in the hot, broiling sun, there being no way of effecting disinfection of the dressings, instruments, etc., except with a kettle of questionable cleanliness. Heat was resorted to exclusively in effecting sterilization. At a certain range he is satisfied that bullets from both of these rifles will inflict injuries to the long bones and produce more or less comminution. In one instance a young soldier was shot through the tibia two inches above the ankle-joint with a Krag-Jörgensen rifle and the hole through the bone resembled very much one made with an ordinary drill. The shot was fired at a range of a thousand yards, but there was no comminution whatever.

The value of the first-aid dressing cannot be overestimated. In Cuba the military surgeons were hampered in their work by lack of dressing material; also, imperfect ambulance facilities. Hundreds were wounded and nearly 300 were killed in three days; consequently the medical department was taxed to its utmost capacity in taking care of the wounded with the limited facilities at its command. In this war, with an insufficient number of medical officers at the front as shown at the time, men occasionally had to wait for hours, and in a number of instances more than a day before they were picked up and the first dressing applied. It was in those cases that suppuration most frequently occurred. In Porto Rico it was different. General Miles, who had command of the invading army, took every precaution looking to the welfare and the efficiency of the medical service. He felt the need of a medical adviser and often consulted him. The reverse was the case in Cuba. In Porto Rico affairs were conducted near the fighting line. The ambulance corps was in readiness and ambulances were to be had in abundance. The moment a man was shot he was carried to the rear and a first-aid dressing, always on hand, was properly applied, and of about forty cases of all the wounded brought back from Porto Rico on the hospital-ship "Relief," there were only two cases of suppuration, a remarkably small percentage, proving conclusively the value of a timely, efficient, first-aid dressing in preventing wound infection.

The small-caliber bullet hardly ever, if ever, carries with it pieces of clothing or any other infectious substance. The bullet itself is practically aseptic. In the majority of cases where wound infection occurred it was due to the subsequent too frequent change of dressings and unjustifiable attempts to probe the track of the bullet. It is unjustifiable, certainly unscientific, to resort on the battle-field to the probe as an instrument of diagnosis.

He has seen a number of cases of gunshot wounds of the abdomen recover without laparotomy. He believes he was the first one to place himself on record years ago, that a man shot through the abdomen from before backward on a level with the umbilicus or above, has a fair chance of recovery without operative interference. It is in those cases that the intestinal canal not infrequently escapes injury. In four out of sixteen experiments, made for the special purpose, careful, subsequent examination of the contents of the abdomen showed absence of visceral lesions which would have demanded a laparotomy. Such are the cases that recovered during the late war. In almost every instance the bullet wound was on a level with or above the umbilicus. The reverse was the case when the bullet traversed the abdominal wall below the umbilical level, and particularly if it passed through the abdomen transversely or obliquely.

There is one part of the surgical treatment of the wounded which was imperfectly performed, *viz.*, the want of early immobilization of fractured limbs. At the front he could find no plaster of Paris, which should always accompany a fighting army. At Siboney he was furnished with plaster of Paris, but it would not set. Plaster-of-Paris dressings, therefore, the sheet anchor of the military surgeon in the treatment of compound fractures, were lacking or imperfect. Surgeons had to do the next best thing—search for splint material, and fortunately, in Cuba, Nature was very kind to the military surgeon in this respect. The supply of wire splints was limited, but the cocoa palm was abundant, and in the sheath of the cocoa-palm leaf is found a most excellent material, in that it is somewhat plastic and porous; it was utilized to great advantage in the immobilization of gunshot fractures.

In contrast to the experience in the Civil War he found in the Spanish-American War that penetrating gunshot wounds of the knee-joint, of the hip-joint, and of the larger joints, recovered promptly, never proved fatal in the absence of wound complications. The men recovered, as a rule, with useful joints.

When he came to Montauk, where he was on duty for four weeks, he had an excellent opportunity to study the conditions of the returned soldiers, of which there has been so much said, particularly in the yellow press. At this camp he did surgery of a peculiar kind, and his experience there perhaps would be of more value to life-insurance companies and their medical examiners than what he said in reference to gunshot wounds. When the

army of Cuba returned, it was an army of patients, not of soldiers. They were all anemic, emaciated, and, with few exceptions, brought with them, as an undesirable inheritance, malarial intoxication. In almost every instance physical examination showed enlargement of the spleen. As the result of infective substances in the gastro-intestinal canal, he met at Montauk with numerous instances of surgical affections directly traceable to intestinal infection. He found a number of instances of enormous ischiorectal abscess, anal fistula, hemorrhoids, ulceration of the rectum, varicocele, and hernia. The prevalence of peri-anal and para-rectal suppurative processes is justly attributable to antecedent attacks of catarrhal proctitis, from which almost every one of the soldiers suffered at one time or another. It was at Montauk where he believes he was of most service to the troops, being placed in charge of the surgical department of an enormous national camp filled with thousands of sick soldiers.

He is positive, as far as the Illinois troops are concerned, that not a single private was sent to the front with hernia. Exceptions were made in the case of officers. Speaking of privates, the examination of them was so rigid that he was sure not a single hernia escaped attention, and yet some of the men are coming back with hernias. He was astonished at Montauk at the number of cases of hernia that the soldiers claimed to have contracted during their short service. What is the cause? The fact remains, that the men were never exposed to forced marches; the longest march in Cuba was from Siboney to the front at Santiago, a distance of nine miles. The prevalence of hernia in the returning soldiers must he ascribed, therefore, to the debilitating effects of the campaign and of disease; to the relaxing influence of the climate; to the disappearance of fat in the region of the inguinal canal. In the near future many of the mustered-out men will apply for pensions for the defect he has just mentioned. In an examination of ten thousand men at Camp Tanner, he found varicocele with great frequency in men of military age, as from eighteen to forty-five. At least twenty-five per cent. of the applicants for military service were affected with varicocele. In not more than two hundred out of the ten thousand did the enthusiastic and ambitious recruits acknowledge that they experienced any inconvenience from this affection. He, therefore, believed at that time that varicocele of moderate size, without symptoms, should not disqualify an otherwise well-built man for military service. He has every reason now to believe that the position he took then was the correct one, judging from his observations of the men who are returning.

DR. WILLIAM CUTHBERTSON read a paper on "The Enteric Diseases of the Army Camp in Their Relation to Life Insurance." He said it was the province of the life-insurance examiner not only to pass upon the present condition of the applicant's health; the probability of his dying in a short time from some acute disease, but also as to the probable effect on his life expectancy of any disease the applicant might have had. Camp diarrhea and dysentery are two of the most important of these diseases. The history of all armies operating in all parts of the world shows that camp diarrhea, typhoid fever, and dysentery are the most prevalent disorders. They exist to a greater extent, however, in campaigns in very warm or hot countries. The records of our Civil War show that diarrhea and dysentery were more frequent and fatal in the Central region than in the Atlantic and Pacific regions. On the contrary, in civil life intestinal inflammation is more prevalent in the Northern, Middle, and Western States, than in the Southern. During the recent Spanish-American War, while his regiment, the First Cavalry, was stationed in Illinois, the universal intestinal complaint was constipation; while almost immediately after their arrival at Chickamauga Park, Georgia, diarrhea began. This was so invariably the case that whenever a batch of recruits arrived from home, one would hear a member of the Hospital Corps remark, "There comes more diarrhea." The summer months of June, July, and August are those in which the greatest number of cases occur, and the mortality is the highest.

Enteric fever proved to be the scourge of the late Spanish-American War. The greatest mortality did not occur where expected, namely, on a foreign soil, from bullet wounds and yellow fever, but right at home in large camps, where every appointment should have been up-to-date, with every appliance modern sanitary science could devise. This deplorable result can be directly chargeable to the Medical Department of the Regular Army.

A wet soil, damp weather, the presence of large quantities of fecal and decomposing matter, and large numbers of men congregated together, furnish a beautiful combination of circumstances for the development of this disease. The presence of hucksters in the camp seemed to be responsible for the spread of typhoid fever in no small degree. The eatables which they hawked from regiment to regiment, became infected, and in this way was the disease transmitted. At Camp Thomas, Georgia, part of the water-supply was taken from the Chickamauga River, the intake pipe being situated only a few yards above the point where one of the large camp drains emptied into the river. The rest of the water-supply of this camp was obtained from springs and wells located in different parts of the grounds, which soon became infected from the leakage through the already infected soil. Finally, the men themselves invited an attack of typhoid fever by their mode of living. They slept on the ground, very often four in a tent, the tent poorly ventilated, and very frequently closed up all day. They would do this in spite of all orders and warnings. They would buy food from hucksters and drink river water, in defiance of all advice to the contrary. Not only the water, but the soil, and even the air of these large camps were undoubtedly infected with the typhoid bacillus.

The average mortality of selected risks—and all the soldiers in the late war could be classified as selected risks—is four or five per one thousand per annum. The latest returns show the mortality of the American Army to have been ten per one thousand for a period of six months, or four to five times greater than it should be. These percentages should settle definitely the question of

the desirability of the soldier as an insurance risk in the negative. Our woods and plains teem with good material for soldiers; we have an unlimited number of first-class medical men and sanitarians. When the army is reorganized it will be put in such a condition that during any future campaigns the life and health of the soldier will be as well protected as if he were under his own vine and fig-tree.

In the October "Bulletin" of the Department of Health, City of Chicago, recently issued, there appears an abstract of a very elaborate and exhaustive report by Dr. William J. Class, medical inspector, on the recent appearance of cerebrospinal fever (epidemic cerebrospinal meningitis of Stillé) in Chicago, 1898. The full report will appear *in extenso* in the annual report of the Commissioner of Health. Thirty-eight cases are cited which occurred under the observation of a number of skilled diagnosticians. All uncertain and doubtful cases were eliminated. We give a condensation of some of the important features of the cases, not less as a timely contribution to the study of a disease which may yet claim the serious attention of sanitarians and health authorities in this country, than as an index of the quality of the work done and the interest and ability displayed by the members of the medical staff of the Chicago Department of Health.

Although the symptomatology of cerebrospinal fever has been exhaustively treated in descriptions of epidemics occurring elsewhere, yet as almost every epidemic offers some distinctive feature, a closer and more careful consideration of the symptoms met with in these thirty-eight cases may be useful. Headache was found present in all of them where a complete history could be obtained, it affecting the entire head, being most severe in the occipital region. In four cases severe backache caused the greatest distress to the patient. In three instances abdominal pain was noted; in two cases there was hyperesthesia of the greater part of the body, so intense in one case that the slightest touch would throw the patient into convulsions. In one case the pain was chiefly referred to the chest, without there being any objective signs of any diseased condition in the thoracic viscera; another patient complained of boring pain in the bones, resembling that of osteomyelitis. Tenderness in iliac and splenic areas was noticed in one case. Attempted flexion of the head usually caused pain. Chills, as an initial symptom, occurred in seven out of the thirty-eight cases. In two cases the patients had complained of a chilly sensation several days before the onset of the acute symptoms. In one case a chill, lasting thirty minutes, occurred on the third day of the disease. The majority of the cases beginning with a chill ended fatally. Vomiting, one of the most constant initial symptoms of the disease, occurred in twenty-six cases at the onset, while in four cases it occurred during the first days of the disease. The tongue was coated in the majority of cases. Trembling of the tongue was noted often on its being protruded. This is considered of great diagnostic value. In six cases diarrhea occurred; in nine constipation. The writer emphasized the symptom of difficulty in swallowing. It was noticed in six cases, each of which ended fatally. It must, therefore, be considered as a grave omen in the prognosis. Herpes labialis was the most prominent skin lesion, and was present in twelve cases. One case showed a papular eruption; another a reddish-brown macular eruption. Petechial patches were noted once. Tache cerebri was found in a number of the cases. In thirty cases there was retraction of the head, varying in degree. The eyes were more or less affected in a large proportion of cases. The ocular manifestations varied from a simple congestion of the conjunctiva, which occurred in six cases, to trophoneurotic ulceration of the cornea and destruction of the eye in one. In two there was purulent conjunctivitis. One showed on ophthalmoscopic examination a cupped disc. The pupillary symptoms were not constant; in five cases they were dilated; in two of these the dilatation was more marked in one eye than in the other; they were contracted in four. Dilated in one eye and contracted in the other in one case. Nystagmus was observed five times; paralysis of the muscles of the eyeball once, the eye remaining fixed. Strabismus occurred in four cases, in one instance being transitory. Paresis of the right external rectus was noted once. In one case there was absolute blindness extending over a considerable period of time without any apparent lesion to account for it. Puffiness of the eyelids occurred in two of the cases, and diplopia once. Photophobia was observed in a comparatively small number. In twenty cases the patients became delirious; robust young men violently so. In some instances hallucinations were present resembling those of delirium tremens. In two cases the mental faculties were seriously impaired after recovery from the acute symptoms had taken place. Paralysis of all of the voluntary muscles of the body was observed in two cases shortly before death. Paralysis of the facial muscles on the left side was also noted in two instances, and paralysis of the right hand once. In two cases contractions of the muscles occurred. In three there was muscular twitching, chiefly in the extremities. Tremor of the hands was observed in two instances. Involuntary evacuations of urine and feces during the course of the disease was noted in six of the cases. Subsultus tendinum was found twice. Convulsions were rare in adults, but frequently at the onset in children.

The state of the reflexes was not constant; as a rule, they were not perceptibly altered. In five cases the knee-jerk was exaggerated, and in three it was diminished. In one it was entirely absent, while in another it was absent on one side and increased on the other. The cremasteric reflex was absent in one case; increased tricipital reflex was noted in one instance. The causation of this variation in the reflex action has never been satisfactorily explained.

In twelve cases there was retraction of the abdominal walls, producing the condition described as "boat-shaped." Tympanites was present in three cases, and in one of these the abdomen was markedly tender. Splenic enlargement was observed in four cases. The liver was found enlarged in two instances. Gurgling in the iliac fossæ was elicited in two cases examined for this rather unreliable symptom.

Joint affections were encountered in five cases, varying in severity. The joints chiefly affected were the wrists, and next the ankle-joints. A careful blood analysis was made only in a limited number of cases; in all instances leucocytosis was found to exist. In one case pigmented leucocytes were found, together with a few extra-corpuscular bodies containing pigment. Widal's test was generally negative, although in one or two instances a partial reaction was noted. In seven of the cases the urine was albuminous; in one sugar as well was present. An excess of earthy phosphates was noted once. In none of the cases where albumin was discovered were casts found. Cylindroids were found in one case, the urine being otherwise normal.

True lobar pneumonia, as a coincident lesion, was noted in two instances; in both, however, the symptoms of meningitis predominated. Other symptoms were found in five cases, chiefly diminished resonance, which could not be properly explained; this condition was encountered in three cases. A blowing systolic murmur at the apex beat occurred in two cases. Cheyne-Stokes respiration was noticed in one case during the course of the disease, and in several instances shortly before dissolution took place.

The pulse and temperature curves presented the same variations as those described by Wunderlich. The initial symptoms were accompanied by a rise in temperature; this rarely exceeded 102° F. during the first forty-eight hours. In some cases this initial rise was followed by a period of three or four days during which the temperature would remain normal, after which there would be another rise. An ante-mortem rise in temperature was noted in three cases, in one of which the axillary temperature was 109° F. There was no relation between the temperature and the pulse. The characteristic feature of the pulse in epidemic meningitis is its slowness, although this rule is not constant. In one instance the patient had a temperature of 105° F.; the pulse at the same time was only 80. Within a few hours previous to death there was, as a rule, a great increase in the frequency of the pulse, even in those cases where it had been slow during the course of the disease. In volume the pulse was usually full; a dicrotic pulse was seldom met with.

Ear troubles, on which special stress has been laid by previous observers, were only noticed in a small number of cases. Some deafness was encountered comparatively often, and in one or two instances suppurative middle-ear disease, but aside from these there was an almost complete absence of aural complications. Lesions of the nasal and pharyngeal mucous membranes were also infrequent in their severe forms, although redness or a slight catarrhal condition occurred in a number of the cases. Epistaxis was found in one instance. Bulging of the fontanels occurred, as a rule, in younger children, in one case the intracerebral accumulation of fluid causing a considerable increase in the circumference of the skull. In protracted cases convalescence usually found the patients greatly emaciated and exhausted, from which they recovered very slowly, some of the young children, in fact, succumbing from inanition after the acute symptoms had subsided.

The average duration of the cases with recovery was four weeks. Some ran a much shorter course, recovery taking place within two weeks, while in others it was delayed from six to eight weeks. Relapses were noted in several instances. In the fatal cases death usually took place within two weeks. Cases of "meningitis cerebrospinal siderans," in which death takes place within a few hours or days, were very rare during the epidemic. Of the thirty-eight cases described, twenty-five ended fatally, a mortality of sixty-five per cent. This figure is far from correct when applied to the entire number of cases in the city, as meningitis is not properly a "hospital disease," comparatively few cases being sent to the hospitals, and these only where the disease was severe. This explains the apparently excessive mortality, as the cases were almost exclusively taken from hospital records. Mild cases not requiring hospital care were very frequent, and if these were averaged up with the more severe cases the total mortality would probably not exceed twenty per cent.

During the Chicago epidemic fifty-one houses where cases of meningitis had occurred were inspected. In twenty-one of the houses or their surroundings unsanitary conditions were found; in some instances very bad. In one house where a fatal case occurred nine families were living in a ten-room house which was littered with filth of every description. Defective plumbing was discovered in a number of instances, and remedied through the Health Department. In eighteen of the houses the sanitary condition was fair, while twelve were in a good condition. The majority of the cases occurred in the poorer quarters, inhabited chiefly by foreigners.

From a consideration of the present knowledge of epidemic meningitis the writer arrives at the following conclusions:

1. Epidemic cerebrospinal meningitis is to be classed among the contagious diseases, belonging to the same category as phthisis pulmonalis.

2. Unsanitary conditions exert great influence in affording a proper nidus for the growth of the germs of this disease.

3. Health authorities should receive notice of the occurrence of a case of this disease, in order that sanitary defects may be remedied.

4. Persons afflicted with this disease should, whenever possible, be isolated, and all evacuations should be rendered sterile by the use of antiseptics.

INJECTION OF GELATIN SOLUTIONS TO CURE ANEURISMS—DIVISION OF CARDIAC ADHESIONS—RESECTION OF THE CERVICAL SYMPATHETIC FOR EXOPHTHALMIC GOITER—CANCER OF THE PELVIC COLON—COMPRESSION OF THE HEART FOR SYNCOPE—POISONING FROM SALICYLATE OF SODA—SCURVY FROM STERILIZED MILK—TWELFTH FRENCH CONGRESS OF SURGERY.

AT the Academy of Medicine October 31st, LABORDE said that the fatal results which have sometimes followed the injection of solutions of gelatin for the cure of

aneurism may be due to the presence in the solution of little solid particles, which, acting as foreign bodies in the circulation have excited coagulation in different vessels. This has been accomplished experimentally in animals when the gelatinous solution has been injected into a vein. One ought to use extreme care to obtain the purest possible gelatin and to make the injections either into the aneurism itself or into its immediate vicinity.

LANCEREAUX denied the presence of solid particles in gelatinous solutions, and said that this theory was unsupported by evidence. If the solutions are injected subcutaneously they are not introduced immediately into the veins but are absorbed by the lymphatics and passed through them into the blood without exciting coagulation. In order that blood should coagulate two things are necessary, viz., that the wall of the vessel in which it is contained should be imperfect, and second, that the flow of blood should be sluggish. These two conditions are realized in the aneurismal sac but not elsewhere in the circulatory apparatus. There is every reason to believe, therefore, that the coagulation is confined to the aneurism.

At the Surgical Society, October 26th, DELORME advocated the division or the destruction of adhesions between the heart and pericardium when such adhesions cause grave symptoms. Numerous autopsies show that the separation of such adhesions without damage to the cardiac muscle may be easily accomplished provided they have not existed too long. Autopsies upon old people where the adhesions have been in existence for many years show that under certain circumstances their division would be practically impossible, but if the adhesions are well localized, even though old, they might be safely divided. If the clinical signs show beyond a doubt that adhesions have formed between the heart and pericardium, a linear pericardotomy is indicated. An incision 2½ to 3 inches in length is made at the level of the fifth costal cartilage, and the pericardium is opened horizontally a little above its attachment to the diaphragm. The superior margin of the wound being lifted, an attempt is first made to free the right side of the heart from adhesions. If they are everywhere present but are capable of easy division a second linear incision may be made in the fourth interspace, and the fourth section of the costal cartilage resected if necessary, with possibly a portion of the third. Adhesions which are not general should be sought out with the finger and divided with blunt-pointed scissors. If the adhesions are too extensive and firm to allow of separation, the pericardium should be divided on a level with the diaphragmatic attachment clear to the apex of the heart. Even this slight operation will be found of great benefit.

TERRIER said that in several operations upon the heart, incisions far greater than that proposed by Delorme had been made without difficulty. Even a portion of the sternum has been sacrificed. In conclusion he said that he believed that one need not hesitate to make an incision of whatever length is necessary to meet the conditions.

GERARD-MARCHANT spoke of partial or total resection of the cervical sympathetic nerve for exophthalmic goiter. He reported seven cases of his own and thirty of other surgeons. It is by no means easy to find the cervical sympathetic. Three ways of doing this have been proposed; one anterior to the sternomastoid muscle, one through this muscle, and a third posterior to it. The last is the best. By this route the jugular is exposed and plenty of room is easily obtained by simply dividing the superficial fascia up to the mastoid process if necessary. The common carotid and the pneumogastric come into view, or if not they must be found before search is made for the sympathetic nerve. The superior cervical ganglion is usually found without difficulty and from it the nerve cords may be traced downward and removed. Statistics seem to show that a partial resection of the cervical sympathetic gives equally as good or even better results than a total resection. Of the thirty published cases, twenty patients were benefited by operation. The speaker himself had two complete cures, two improvements, two failures, and one death. Taking the whole thirty-seven cases together there were five deaths in a short time and three at a later period. Four of the early deaths were caused by influenza-pneumonia, pulmonary congestion, syncope, and erysipelas. The fifth occurred in an alcoholic subject on the third day after operation. It was preceded by febrile symptoms and an extreme amount of agitation. In view of these facts, the operation in itself cannot be considered a particularly dangerous one, and when it is taken in account that the disease is in itself fatal sooner or later, and is associated with very grave complications, such as disturbances of the vision, one ought to advise operation when medical treatment has failed. Three operations have been practised for exophthalmic goiter: exothyropexy, devised by Poncet, and now given up by him; thyroidectomy, which according to the published statistics, has given few cures and a considerable number of sudden deaths from operation, and partial resection of the cervical sympathetic which, under these circumstances, is a valuable method of treatment.

At the session of November 2nd, QUENU discussed cancer of the pelvic colon. He divided this portion of the large intestine into three parts: the ileopelvic colon, which is relatively immovable, the sigmoid flexure properly so called, and the rectosigmoidal. Cancer in this third portion may be touched with the finger, even though five or six inches above the anus. The symptoms it produces are practically those of cancer of the rectum. Cancer of the ileopelvic colon gives an iliac tumor which may easily be mistaken for inflammatory thickening, by no means uncommon in this situation. Inflammatory thickening is smooth; that due to the neoplasm is uneven. Owing to the mobility of the sigmoid flexure cancer in this situation gives rise to a variety of symptoms. Abdominal palpation is pretty accurate in very thin patients. In stout ones such a tumor may escape the examining fingers. If the case is a doubtful one, it is better to resort to an exploratory operation rather than by delay to run the risk of metastasis. In a few rare cases the tumor

has escaped observation, since its growth was only sufficient to make good the atrophy of that portion of the intestine. Such a tumor may escape recognition even when an exploratory laparotomy has been made. Quenu cited such a case occurring in his own practice, where at autopsy there was found a small circular cancer of the sigmoid.

TUFFIER, encouraged by the success which has been obtained in dogs, by rhythmical compression of the heart for cardiac syncope, applied the same method to a man aged twenty-four years. This patient was operated upon for acute appendicitis. All went well until the fourth day. Then during the surgeon's visit the patient was attacked with syncope, and the heart absolutely stopped beating. Artificial respiration, combined with rhythmical traction of the tongue, failed utterly. The third intercostal space was incised, the pericardial sac was opened, and the ventricles were compressed between the thumb and finger some sixty or eighty times, when the arterial pulsations returned, and the patient opened his eyes. They ceased again in two or three minutes, but once more returned after the heart had been a second time subjected to compression. The pulsations, however, soon ceased, and did not return in spite of every effort. The autopsy showed that there was a large clot in the pulmonary artery.

HENNEQUIN presented a report upon the treatment of old dislocations of the shoulder. He advocated operation only in exceptional circumstances. Experience showed that success often followed a second or third attempt at reduction, even when previous attempts made with an anesthetic had failed. This treatment ought, therefore, to be very thorough before operation is resorted to. The fibrous tissues which offer resistance to reduction appear to form less rapidly in women than in men, hence attempts at reduction of dislocations in women may be successful several months after the accident.

SCHWARTZ mentioned an interesting case of intestinal obstruction which developed in a pregnant woman aged thirty-two years. Operation was performed, and a loop of small intestine was found firmly fixed behind the uterus by old adhesions to the broad ligament. With the separation of these adhesions gas and fecal matter passed through the intestines, and the patient recovered. The five-month's-old fetus was expelled the night after the operation.

At the Medical Society of the Hospitals, October 28th, RENDU said that a woman aged thirty years had been given 6 grams (90 grains) of salicylate of soda, to be taken in six doses through the day. She had suffered about six weeks from an acute attack of rheumatism, with high fever and much pain, but neither cardiac nor renal complications were present, as far as could be observed. The following day she felt much better, and the fever was abated. The joints were still swollen and painful, and the medication was continued until eight o'clock that evening. Without warning the patient suffered a chill, and then became violently delirious, having hallucinations of sight and hearing. This delirium persisted for thirty-six hours, and then disappeared. The patient was absolutely without recollection of anything that occurred during the period of delirium. During this period the temperature was not at all elevated, the pupils were contracted and unequal, while the urine was scanty and contained a great quantity of albumin and indican. The salicylate of soda was stopped as soon as the delirium appeared, and the patient recovered, not only from the delirium, but from her rheumatism.

ACHARD thought that the delirium might have been due to the scanty secretion of urine.

BERNARD once gave a woman aged forty-five years, who suffered from acute rheumatism without complications, 12 grams (180 grains) of salicylate of soda in divided doses. The patient was neither alcoholic nor neurotic, and there was no albumin in her urine. The treatment brought on an attack of acute mania, with hallucinations of sight and hearing. At the end of forty-eight hours her state had again become normal.

At the session of November 4th, NETTER described a case of scurvy which occurred in a child aged one year that was fed upon sterilized milk. All the classical symptoms were present: anemia, weakness of the lower limbs, subperiosteal hemorrhages, lesions of the gums, etc. The child was put upon a diet containing meat, orange-juice, pureé of potato, etc., and quickly recovered.

At the Twelfth Congress of Surgery, October 17, 1898, GUYON and ALBARRAN read a paper upon "Nephrotomy," an operation which is to-day done (1) to explore the kidney or the ureter; (2) to permit the extraction of a calculus; (3) as a preliminary to certain operations upon the pelvis or ureter. The curved or oblique lumbar incisions are the best. When the kidney has been opened the surest method of exploration is this: one finger may be introduced into the pelvis of the kidney, to palpate against another finger on its outside. Even this method may fail to detect some renal conditions, for example, miliary tuberculosis. In one case a small cancer was overlooked until the microscopic examination of some false membrane revealed its presence.

A permanent opening in a kidney—nephrostomy—may be established either through an abdominal or lumbar incision. The latter method is less dangerous, is easier to accomplish, and facilitates future operations if such are necessary. To avoid perirenal suppuration the lips of the renal wound should be stitched to the anterior and posterior margins of the lumbar incision. The object of nephrostomy is to drain a septic or aseptic collection, or to re-establish urinary secretion in a condition of anuria.

The urine which drains from a renal fistula is practically normal if there was no obstruction to its flow before the operation. On account of the constant flow of water outward severe infection of the pelvis is not likely to occur. The parenchyma of the organ is affected scarcely at all, and in anuria renal secretion begins as soon as the operation is performed. If before nephrotomy was performed there was a condition of obstruction to the urinary flow the urine will return to its normal condition after the fistula has been established, more or less rapidly and perfectly, according to the nature of the obstruction, partial or complete, simple or septic, etc.

In calculus obstruction it is necessary to consider not only the mechanical obstruction, but the congestive phenomena, and the suppression of urine due to reflex influences. Usually, in calculus anuria the opposite kidney ceased to act before the anuria appeared. Sometimes this kidney looks normal but even then it will be found to present signs of nephritis which rendered it susceptible to reflex influence.

Ureterotomy may be performed for calculus, but it is difficult and sometimes unsatisfactory, and is not to be preferred to nephrostomy. Pyelotomy is feasible when the calculus is surely in the pelvis, but recovery is less prompt than when the incision is made through the parenchyma.

In uronephrosis it is better to make an incision than to remove the kidney. But a fistula is not the ideal operation, and attempts should be made to remove the cause of distention by ureteral catheterization, nephrorrhaphy, ureterotomy, or ureteropyelostomy. If the other kidney is damaged and it is necessary to spare the parenchyma of this one, nephrotomy is indicated, and conservative operations should be undertaken with great prudence. Nephrectomy under such circumstances is contraindicted, but may be performed upon a kidney whose secretion is of limited value, if the other kidney is active. In simple pyonephrosis a renal fistula is preferable to any anastomosis intended to reestablish the normal course of the urine. After suppurative symptoms have subsided such reparative operations may be undertaken.

In tubercular pyonephrosis a fistula is more troublesome, and its benefits are often of short duration. If the affected kidney has no value, and the opposite one is sufficient to sustain life it is better to remove the diseased one. Usually there is tuberculosis of the pelvis and parenchyma as well. "We have many times performed nephrotomy for tuberculosis, but have never seen the fistula close, and invariably the patients have died within two years." If one can assure himself of the good state of the other kidney, it is doubtless better to perform a nephrectomy. It has not been shown that a secondary nephrectomy is less dangerous than a primary one. Published statistics show that the mortality from nephrectomy for tuberculosis is twenty-eight per cent. for primary and thirty-four per cent. for secondary operations. The mortality of the primary operations of seven of the best European surgeons is only ten per cent., and that of eighty-four nephrotomies performed by different surgeons is seventeen per cent. Nephrotomy in tuberculosis is an operation of necessity, but one may count upon great amelioration of the symptoms after the fistula has been established.

ALBARRAN spoke of the treatment of fistulas after nephrotomy. If a urinary fistula persists when the pelvis is not distended, it indicates either that the pelvis was injured at operation, or that there has been an infection following operation. If the pelvis was much distended before the nephrotomy, the ureter may remain impervious on account of a fold in its insertion. This may perhaps be overcome by leaving a catheter *in situ* for a time, or by establishing an anastomosis between the pelvis and the ureter. If these measures fail, or if the ureter is not permeable for a catheter throughout its whole extent from below upward, a catheter is passed as far as possible, and the ureter is then cut down upon and every effort made to restore the continuity of its lumen before a nephrectomy is resorted to. If the urine contains pus search should be made for perirenal purulent foci. If such are present it may be possible to drain them and heal the kidney without removal. One should not be in a hurry to close up a fistula after operation. By waiting some time the ureteritis will often recede, so that the conditions for success of a plastic operation are greater.

JONNESCO reported that he had performed fourteen hemicraniectomies, and two frontoparietal craniectomies, with three deaths inside of six weeks after the operation. Six patients were cured, one of acute mania and epilepsy, two of old traumatic epilepsy, one of Jacksonian epilepsy, and two of hysteria with prostration and idiocy. One hemiplegic epileptic, and one microcephalic idiot, were improved. The operation was six times unsuccessful upon two epileptics with acute mania, and four idiots.

CALOT advocated the treatment of tubercular cervical adenitis by means of injections of chlorid-of-zinc solution, one part to fifty of water. Two to three grains (30 to 40 minims) are injected with a very fine needle, every third or fourth day. The treatment will cause the disappearance of the gland, without any permanent scar, provided only that the skin has not yet become involved in the inflammation at the time treatment was commenced.

TUFFIER practised ligation of the uterine arteries for cancer, in seven patients. The best result was that life was prolonged for two years before yielding to metastasis. Neither in these cases nor in certain fibromyomata of the uterus, was there any apparent curative effect. The utmost that can be hoped for from this treatment is the slowing of the morbid process.

SOCIETY PROCEEDINGS.

NEW YORK STATE ASSOCIATION OF RAILWAY SURGEONS.

Eighth Annual Meeting, Held at the New York Academy of Medicine, Thursday, November 17, 1898.

THE morning session was devoted to the special topic

SURGICAL SERVICE ON RAILWAYS,

and the discussion was participated in by prominent railway surgeons and officials, including railway presidents, division superintendents, attorneys, and claim agents. The proceedings, of great practical interest to the railway surgeon, were scarcely of sufficient general interest to warrant a report of them here.

The afternoon session was taken up with the election of officers and the reading of papers.

The officers elected for the ensuing year are: President, T. D. Mills of Middletown; first vice-president, J. L. Eddy of Oleon; second vice-president, G. N. Hall of Binghamton; secretary, C. B. Herrick of Troy; treasurer, H. P. Jack of Canisteo.

DR. C. B. HERRICK of Troy, the retiring president, delivered the President's address on

SURGICAL TECHNIC.

He considers that the more simple the preparatory technic the better. Surgeons who go to extremes in their asepsis obtain no better results than those who observe carefully though not over minutely the ordinary details of surgical cleanliness. The old surgeons, even before the days of antisepsis and asepsis, did not lose by any means the majority of their patients, and some of their statistics are worthy to be referred to yet. A marble operating-room and all the expensive accessories that go with it are not indispensable to good and successful surgery, and the fact that it may be impossible to secure any but the simplest conditions of cleanliness for an operation, must not be allowed to discourage the surgeon from doing all in his power under such simple conditions to save human life especially in emergencies.

DR. HENRY FLOOD of Elmira read a very practical paper, entitled

REMARKS ON AMPUTATION OF THE FOOT.

The foot is so important to the wage-earner that every half inch saved below the mediotarsal articulation should be considered of the greatest value. The operator should be bold to save, not to amputate. Accident is no respecter of anatomy, and no hard and fast lines of amputation should be observed. There are those who suggest a Symes' amputation for a crushed foot, because a very useful artificial foot with a not ungraceful action in walking can be secured to supply the missing member. But such prothetic apparatus is expensive, needs frequent renewing, and is not nearly as useful for the workingman as the smallest part of the foot that can be saved. Never go higher up to amputate because of any claims as to more adaptable prothetic apparatus; with the advance in that regard in our day, it is always a mistake. As in amputations of the hand save all tissue possible without regard to classic types of amputations. Treat the foot as a whole and amputate where necessary. As far as possible take plantar flaps, as the tissue of the sole is better suited for the end of the stump, but make use of dorsal flaps when the other is not available. Be careful of the Esmarch bandage and of tourniquets. They produce an artificial anemia and deceive as to what tissue is really alive, besides the temporary interference with the circulation may lower the vitality or eventually cause the death of tissue that would otherwise live. In amputating it is better to pick up and clamp or tie the cut vessels at once, except after severe hemorrhage, when it is necessary to avoid even the slightest blood loss, when some obstructive method of hemostasis may be employed.

DR. G. N. HALL of Binghamton read a paper, entitled

IS A RAILWAY SURGEON JUSTIFIED IN PERFORMING PIROGOFF'S AMPUTATION?

He considers the operation unjustifiable because the blood-supply to the flaps is almost necessarily interfered with under normal anatomical circumstances by the incisions prescribed for the amputation. Besides the nutrient foramen, the os calcis is below the point where the main artery is cut, so that necrosis of the calcaneum will ensue unless good union with the tibia should be secured immediately. Statistics show that it is the amputation of the foot that has to be oftenest repeated, and one-third of the cases in which it has been done have been followed by failure or death.

DR. JOHN WYETH, in discussing the two papers on amputations of the foot, said that he thoroughly agrees with the conservative spirit that would save every bit of tissue possible. He does not believe in immediate amputations and very seldom does a primary amputation in crushing injuries. To have to repeat the operation later he does not consider in these anesthetic days as a reflection upon the surgeon's skill. It does show that he fails in the proper direction, that of over conservatism. He finds position a great aid in controlling hemorrhage, the foot being raised or the patient's body lowered, and he is able to dispense with an Esmarch or tourniquet. For years he has treated the foot in amputations as if it were one bone, and he is glad to find men of large practical experience agree with him. He prefers Symes' to Pirogoff's amputation, though a Symes' stump will require an expensive artificial foot and frequent renewal of it, so that he makes his declaration only for reasonably well-to-do patients, not for laboring men.

DR. W. L. ESTES of Bethlehem, Pa., said three practical questions come up for solution when it is proposed to do an amputation of the foot: (1) Where can the flaps be obtained? (2) What form of stump will be best for this particular patient in after life? (3) What amputation will be followed by the shortest present disability? This last question is especially important in the case of the laboring man. The foot should be considered as a whole in any amputation, the line of section being the lowest that flaps can be got to cover. There are some suggestive things in the classic types of amputations. One not mentioned in the discussion is Mikulicz's for injuries of the heel. It especially enabled the operator to avoid the danger of having in young people a conical stump develop, which is so liable to happen if the amputation is in the leg itself. No attention should be paid to certain instrument-makers' representations as to the advisability of amputating at certain joints. No tissue should be sacrificed to any such false notion.

DR. MANLEY of New York said the surgeon should hesitate to sacrifice any tissue until he is sure it will not live. The reaction should be waited for in order to be assured as to where Nature will draw the line of demarcation between living and non-living tissue. The so-called classic amputations of the foot in the text-books should be wiped out once and for all. They have done far more harm than good. The Esmarch and the tourniquet are to be very charily employed; they have undoubtedly often done harm. A device that has been of great use to him on more than one occasion is what the French call the *desossement* of a toe, the bones of the toe being removed in order to supply tissue to help cover in the end of a stump.

REVIEWS.

A MANUAL OF SURGERY. By WILLIAM ROSE, M.B., B.S. (London), F.R.C.S., Professor of Clinical Surgery in King's College, London, and Senior Surgeon to King's College Hospital, etc., and ALBERT CARLESS, M.S. (London), F.R.C.S., Senior Assistant Surgeon to King's College Hospital, and Teacher of Operative Surgery in King's College, London, etc. New York: Wm. Wood & Co., 1898.

IN their preface, the authors express themselves as intending this work to be an abridged consideration of the subject of surgery, thus supplying a "genuine need." It is a volume of 1144 pages and 392 illustrations, printed in such small type with such narrow spacing as to make it rather trying to read this otherwise interesting and completely handled subject.

In every paragraph the student is made to appreciate the significance of bacteria as factors of disease, consequently etiology, pathology, and therapy are rationally dealt with. The first five chapters give an extensive consideration of surgical bacteriology, yet we fail to find a single chapter devoted to the methods of antisepsis or asepsis; certainly a flagrant omission. Of interest to teachers in this country might be an enumeration of the points in which these English authors are at variance with us. They deprecate the use of O'Dwyer's tube in diphtheritic stenosis for fear of dislodging the membrane. As to appendicitis, however, they side with the majority of us in considering its treatment surgical. A case of carcinoma of the breast, requiring a clearing out of Mohrenheim's fossa, is considered unsuitable for operation. In the abandonment of irrigations in empyema they are in line with our teachings. For hernia they favor Mitchel Banks' operation. The fear of asphyxia when opening retropharyngeal abscesses internally is not founded on clinical experience nor are most of the other reasons potent enough to call for the major operation of external incision.

Certainly the Paquelin cautery has a place in the treatment of certain angiomata. With others of the British school the authors consider colotomy a more favorable operation for carcinoma than excision. After all, these few instances comprise but mooted points, which do not detract from the value of this work as a text-book for students to whom it will commend itself for the reasons stated, besides being one of the latest works on the subject.

AN AMERICAN TEXT-BOOK OF THE DISEASES OF CHILDREN. By American Teachers. Edited by LOUIS STARR, M.D., Consulting Pediatrist to the Maternity Hospital, Philadelphia; Late Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania. Assisted by THOMPSON S. WESCOTT, M.D., Instructor in Diseases of Children, University of Pennsylvania; Visiting Physician to the Methodist Episcopal Hospital. Second Edition, Revised. Philadelphia: W. B. Saunders, 1898.

THIS work, of which the first edition appeared in 1894, is before us in a much revised form. There are new articles on "Modified Milk and Percentage Milk Mixtures," on "Lithemia," and on "Orthopedics." A large number of articles has been rewritten and numerous others have been much amended. It will be necessary here to review only the new articles and those especially revised. As a whole the volume shows the same good qualities which called forth such enthusiastic reviews four years ago.

The opening article by Starr, on infant-feeding and hygiene has been rewritten and is very modern. The writer is evidently in favor of Pasteurization. It will hardly do to call "heating milk at 155° F. for six minutes" sterilization. Starr describes fully all the usual methods of diluting milk, except Rotch's, which is explained in a new contribution by Westcott, who also states in detail his own method of percentage dilution. Leeds gives a good review of the composition of various milks and artificial foods and describes what is meant by "certified milk."

Rochford contributes a new article on "Lithemia," which he considers "essentially an auto-intoxication resulting from the presence of an excess of alloxuric bodies in the body media." He describes two main classes, the gastro-enteric and the nervous, and adds some interesting remarks on the urinary and skin complications. Considering the darkness of this subject, and our lack of exact information as to the causation, we should have preferred to see the article headed "Auto-intoxication," as the author himself suggests.

In the article on measles, by Starr, a description of the buccal eruption, as described by Koplik, has been added. The articles on rubella, varicella and parotitis, by Plant, are exceedingly well written, but we should like to have heard something of the recently described diplococcus of parotitis and less about Bordas' bacilli. Similarly, in the article on pertussis, by Griffifth, some mention of Koplik and Czaplewski's work would have been very welcome.

Morrill has rewritten his contribution on typhoid fever. The present status of the Widal reaction is not properly defined. From the statements made one would be led to infer that the reaction occurs in all cases of typhoid fever, and no mention is made of the occurrence of the reaction in some cases very late in the course of the disease.

Lumbar puncture is not referred to by the author of the articles on epidemic cerebrospinal meningitis and simple cerebrospinal meningitis. It is, however, shortly described by Lloyd in his excellent account of tubercular meningitis. It is rather surprising to find no mention of the intracellular diplococcus and its rôle in the first-named disease.

Brown writes fully and interestingly on diphtheria except in reference to antitoxin. A detailed account of the reduction in mortality after its use and of its dosage is given, but as to how it affects the membrane, the temperature, etc., nothing is said, nor are the succeeding rashes and joint complications mentioned.

We are pleased to see that Packard, in his article on anemia, does not treat of "anemia infantum" as a separate clinical entity. The articles on nervous diseases are admirable. The contribution on cretinism has been

revised by Spiller, whose description leaves nothing to be asked for. He draws special attention to the so-called "cretinoid" cases.

Lack of space prohibits our mentioning numerous other articles worthy of note. The defects we have noted above are almost entirely those of omission and hardly detract from the great clinical value of the book.

WOUNDS IN WAR. By SURGEON-COLONEL W. F. STEVENSON (Army Medical Staff). A.B., M.B., M.Ch., Professor of Military Surgery, Army Medical School, Netley. New York: Wm. Wood & Co., 1898.

WITHOUT purporting to present anything novel, this work was planned "for the use of officers in the three services" (British). Much therein contained is largely a compilation of earlier writers. The high esteem which the author has for Otis' "Surgical History of the War of the Rebellion", is evidenced by the many references to it.

The first chapter is devoted to remarks on weapons, firearms, obsolete and modern, and projectiles and their mechanics. Injuries produced by projectiles of small caliber are discussed in Chapter II., and the author's experiments contrasted with those of Bruns, Demosthen, and Van Coler. Stevenson agrees in the main with the latter two, but rejects the conclusions of Bruns, whose experiments were conducted with reduced charges at fixed short ranges. The author maintains that only results of actual warfare can furnish the *experimentum crucis* for the small bore.

With others he believes in the humane advantages of the mantled bullet; yet he foresaw its inefficiency in "stopping power" when employed against savages—thus forestalling actual experience in the "Chitral campaign" which called forth the "dum-dum" bullet. This being the *raison d'être* for the bullet ought to allay the fears of the Germans, instilled by Bruns, as to its universal use.

Under the general consideration of treatment of bullet wounds, the author favors searching for the bullet only when extensive injuries in themselves demand operations. With his otherwise keen appreciation of the details of antisepsis it is rather disappointing to read the author's recommendation of such an unsurgical procedure as the use of sulphate of iron for hemostasis of capillary hemorrhages. The use of the Röntgen-rays is not mentioned.

In the succeeding six chapters the injuries of special organs and their treatment are discussed with excellent judgment and due regard for the versatility of military operations the exigencies of which will ever minimize much that might be expected from conservative treatment and antisepsis. In the closing chapter the author gives the nine articles of the "Geneva Convention," supplementary to which he rightly remarks: "No military medical service unassisted can in future efficiently carry out the work required of it." He follows this with the astonishing arraignment that in England alone this auxiliary help is more poorly organized than in any other country.

Without wishing to detract from the merits of the treatise we cannot but express our regrets that so much therein is but a reflection of the experience of pre-antiseptic days, and not the experiences of smaller campaigns in Japan, Chitral, Abyssinia, and Greece. However, to those of us recently engaged in the throes of war, this excellent volume from the pen of this specially schooled military surgeon is very instructive reading.

THERAPEUTIC HINTS.

Subconjunctival Injections of Iodin for Choroiditis.—

℞	Iodi pur.	gr. $\frac{1}{6}$–$\frac{1}{3}$
	Potassii iodi	gr. xv
	Aq. dest.	℥ i.

M. Sig. External use.

Of this solution 4 to 5 drops are injected under the bulbar conjunctiva every two or three days, and as the reaction diminishes the amount injected is increased gradually to 10 or 15 drops. A slight degree of chemosis is caused and some pain; the former disappears in 12 to 24 hours, and the latter decreases with successive treatments. Favorable effects are seen in two or three weeks in a diminution of size of the floating opacities and an improvement in vision, especially of central vision, this being true even in cases of muscular choroiditis.—*Sourdille.*

For Acute Dysentery.—SANDWITH of Cairo advises the following treatment: The patient is to stay in bed with flannel over the abdomen, and placed on a diet of boiled milk, rice water, and Seltzer, plus a little whisky. A dose of salicylate of bismuth, 15 grains, is given every 4 hours. The intestine is washed out daily with a quart of boric acid and starch solution, and for a few days daily rectal injections are made with the following mixture:

℞	Cupri sulphat.	gr. xv
	Tinct. opii	gtt. xv
	Amyli	℥ i
	Aquæ	℥ viii–Oii.

M. Sig. For one rectal injection.

A cocain suppository may be inserted afterward if indicated.

For Melæna Neonatorum.—

℞	Etheris acetici	*m.* xxxii
	Aq. sacchari	℥ ii.

M. Sig. One teaspoonful every four hours.—*Seifert.*

Cardiac Stimulation for a Child.—

℞	Spts. etheris comp. . . .	*m.* lxxx
	Tinct. nucis vomicæ . . .	*m.* xl
	Tinct. lavandulæ comp. . .	*m.* lxxx
	Aq. cari . . . . q.s.ad	℥ iv.

M. Sig. One tablespoonful every four hours to a child of eight to twelve years.—*Ashby.*

For Enlarged Lymphatic Glands.—KATCHINOVSKY advocates the administration of the salts named below according to the Botkine method in order to produce nascent iodid of iron within the body since this acts so much more energetically than when given preformed:

a. One dram of potassium iodid in 6 ounces of water.

b. Ethereal tincture of malate of iron.

Add 3 to 20 drops of Solution B. to 2 or 4 teaspoonfuls of Solution A., and give twice a day at mealtime.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIII. NEW YORK, SATURDAY, DECEMBER 10, 1898. NO. 24.

ORIGINAL ARTICLES.

THE NON-MEDICINAL TREATMENT OF CONSTIPATION.[1]

BY GEORGE ROE LOCKWOOD, M.D.,
OF NEW YORK.

THE treatment of habitual constipation is either a simple or difficult task according to the conscience of the prescribing physician. To the medical adviser who aspires to the title, "busy doctor," the problem is one easily solved. A glass of Hunyadi water, Epsom salts in the morning, the much-lauded cascara, at night, some laxative tablet advertised by the pharmaceutical chemist, enemas, suppositories or a prescription containing the familiar combination of aloes, podophyllin, belladonna, and strychnin—these are the remedies ordinarily used to combat this prevalent disorder. The writer does not deny that by these means a patient may be relieved of his constipation, but he does assert in all earnestness, (1) that the laxative drugs so given have no lasting benefit, usually operating only when given in increasing quantities; (2) that a train of subsequent evils is almost certainly set in motion, sure to cause serious, if not irremediable injury to the gastro-intestinal tract, and (3) that constipation can be more successfully treated by following physiological principles and in regulating the diet, exercise, and hygienic habits.

Before entering more fully into the subject it is desirable to limit the discussion entirely to the habitual and chronic forms of constipation. There is no doubt that the remorseful headache that blots from the memory the pleasures of the past may be relieved by the quickly acting Hunyadi. The distended abdomen may become soft and palpable by the gentle dose of oil, and the bilious attack may be mitigated by calomel. These are, however, acute conditions which require acute remedies, and about these and similar cases we shall make no mention.

The question of what constitutes the constipated state is one not easily answered. We have come to the conviction that a daily stool is necessary to health, and yet it would seem as though there were patients whose normal condition produced a stool every second or third day without detriment to any of the functions of the body. To submit such tardy patients to the habitual use of quickening remedies would, therefore, seem wrong. Much better is it to make a rough estimate of the total quantity of the stool, to see for instance if the stool every other day contains two-days' quantity of excreta and whether the patient suffers from his tardiness, before submitting such a patient to treatment. These are cases of apparent, but not of *real* constipation. Better far such a tardy but sufficient stool naturally induced than a daily result from medication. On the other hand, a patient may have a daily stool though of insufficient quantity—a real but not an apparent constipation.

It will be well to divide the discussion into two headings: I. The injuriousness of the habitual use of laxatives. II. The non-medicinal remedies for constipation and their indications. (1) The drugs usually given in constipation are: (*a*) Those given internally (salines, vegetable cathartics). (*b*) Those acting locally (enemas, suppositories).

1. The salines usually depend for their efficacy upon the sulphate either of magnesium or of sodium. Let us take Carlsbad salts as the type, because its effects upon digestion have been most accurately determined. Jaworski[1] has proven that two results follow the continual dosing of Carlsbad salts: (*a*) That the production of HCl. and of digestive ferments is reduced, often to such an extent that their secretion cannot be excited, even by the introduction of food into the stomach. (*b*) That atony of the muscular wall of the stomach results, provocative of serious symptoms of indigestion and difficult of cure. These results are evident six weeks after the beginning of the dosing. Jaworski's conclusions have been corroborated by those of Boas, Ewald, and others and may be accepted as *facts* about which there can be but little dispute. (2) The drastic purgatives, aloes, rhubarb, podophyllin, cascara, and the like act not only in depressing the secretory power of the stomach and in weakening the tone of its muscular wall, as do the salines, but they exert in addition an actual congesting effect upon the gastro-intestinal mucosa. From the congested blood-vessels serum transudes, peristalsis is increased as in all intestinal inflammations and a watery stool results.

[1] Read in the Section on General Medicine of the New York Academy of Medicine, November 15, 1898. For discussion see page 775.

[1] "Uber die wirkung des Karlsbader thermal Wassers auf die Magendarmfunctiv," *Deutsches Archiv f. Klin. Medicin*, Bd. 37.

It is the same process as in cold in the head. The nose runs; we blow it. If we have a fresh cold every day it would not be long before a chronic catarrh would be set up. Just as positive as it is that the continual use of vegetable purgatives produces not only secretory and muscular insufficiency of the gastric and intestinal walls, but an actual inflammation, thus perpetuating the condition we are anxious to relieve. Boas, with all his ripe experience writes: "This is one of the reasons why secretory insufficiency of the stomach is more common in women than in men, although the latter, by reason of the misuse of tobacco and alcohol, are more disposed to gastritis than the women."

The contraindications to the habitual use of salines and vegetable cathartics may be thus enumerated: (1) They are contraindicated in all conditions of diminished secretory power of the stomach (hyperacidity). The only excuse for the use of Carlsbad is the one class of cases with hyperacidity and normal muscular tone, a condition not frequently encountered. (2) They are contraindicated in all conditions of impaired muscular power of the stomach or intestines. One example will show what is meant. We know how common is the condition of gastroptosis and atony combined. The relaxed and displaced stomach reaches one or two inches or more below the umbilicus, and over it may be elicited the splashing sounds when the stomach should be empty, or after the administration of 4 or 5 ounces of water in the fasting condition. Constipation regularly accompanies this condition, and if, for it, salines or vegetable carthartics are employed, the gastric condition is certainly made worse. It is marvelous how these patients improve when these drugs are discontinued and the constipation treated on less heroic lines. (3) They are contraindicated in all conditions of inflammation of the stomach, large or small intestine. In gastritis they regularly reduce secretory activity already reduced and tend to aggravate the gastric inflammation. As to intestinal inflammations the observant physician, especially if he make a practice of examining the stools, will often notice an increase of symptoms of enteritis or colitis, both objective and subjective, after a course of purgatives. Boas says: "I do not exaggerate in the least when I assert that the predominance of *enteritis membranacea* in women is to be referred to the use of more or less unsuitable laxative remedies." (4) Laxatives are absolutely contraindicated in young patients and children owing to the great sensitiveness of the gastro-intestinal mucosa and their proneness to atony of the gastric and intestinal wall. Boas makes emphatic mention of these cases and asserts that diet, massage, and abdominal gymnastics will, without fail, effect a cure.

These objections have led many to the use of simple enemas. An occasional enema is often of the utmost value, but their habitual use is a positive detriment. The sigmoid is distended, its expulsive power weakened, while the long-repeated mechanical irritation diminishes in great measure its sensitiveness, so that reflex attempts at expulsive contraction are markedly lessened.

One other effect is occasionally seen: the rectum and colon are endowed with marked absorbing qualities; the ptomains and other excrementitious bodies in the feces would be rapidly absorbed to the detriment of the system were it not for the diminished fluidity of the stools. If the enema dilutes the feces the poisonous extracts may be rapidly absorbed and serious consequences may occasionally ensue.

Suppositories are useful in inducing regular habits and the natural straining efforts, but their long-continued use produces congestion and irritability of the rectum, congestion of the hemorrhoidal veins, and, in patients with weakened perineal support, a prolapse of the gut, to a certain extent at least. Especially to be avoided are suppositories in young children on account of the stimulating effect in the anogenital region and the possibility of undue genital excitement.

Let us turn now from the destructive to the constructive portion of this paper and consider the treatment of constipation: (1) by diet, (2) by measures calculated to strengthen the abdominal supports, (3) by hydrotherapy, (4) by sedative remedies, and (5) by oil irrigations.

I. *Diet.*—The diet suitable for constipation may be divided into three classes: (1) Fecal-forming food: Coarse vegetables, coarse bread, cereals. (2) Secretion-excitors: Sugars—milk-sugar, honey, fruits, compotes, salts, especially NaCl. (3) Peristalsis-excitors: Cider, buttermilk, fats, organic acids.

Coarse vegetables, such as spinach, Brussels sprouts, turnips, and carrots, should constitute a large proportion of the diet. To avoid irritation of the stomach it is well to have them prepared in pureé form. To this class of foods must be added the coarse cereals. The breads should be of coarse texture and should be given one day old. Porous bread is to be preferred. A very good biscuit is Dohl's dyspepsia cake, somewhat dry, but if moistened with hot water or milk and eaten with a little sugar, really not unpalatable. One biscuit at night is often serviceable without other dietetic rules. As to whether the taking of water with the meals is of benefit is a mooted point. There is no doubt that a glass of cold water on rising in the morning is of

great service in increasing gastro-intestinal peristalsis, but during the meals it is my opinion that little water should be taken. In general the drier the diet the greater the mechanical stimulation of the intestinal wall. This constipation-diet, in its entirety, is indicated in atonic constipation alone. Whenever inflammation exists bulky foods must be excluded and reliance placed on other foodstuffs and remedies. This bulky diet is also contraindicated in cases of muscular insufficiency of the stomach, especially with gastroptosis, as the bulk of the food mechanically overloads the weakened stomach. In simple atonic constipation this diet, while theoretically indicated, can never be carried out in full severity by reason of objective disturbances (distention of stomach and intestines) and of flatulence. Such a diet, moreover, palls, so that meat and other articles of food must be allowed to avoid monotony. This latter indication is most essential in neurotic patients who require a varied diet. Care must be taken in all cases to exclude from the diet all constipating food. This is often overlooked. One glass of claret will neutralize, for example, the laxative effect of an entire meal. Tea must be freshly made and never strong.

II. *Sugars.*—It is not definitely proven whether the action of sugars is through the fermentation they undergo, producing butyric, lactic, and acetic acids which increase intestinal peristalsis, or whether they act as do the salines, in producing a transudation of serum through the intestinal wall. Strauss and Boas incline to the latter theory. Certain it is that we have in this class of foodstuffs a very efficient means of combating constipation. Sugars are best given in the form of honey, milk-sugar, and fruit compotes. The simplest and best remedy I know of is a tablespoonful of honey in half a glass of warm milk on rising in the morning. It very seldom disagrees or diminishes appetite for breakfast. Honey, jam, or marmalade may also be taken with the breakfast roll. Lactose (thirty cents per pound) is to be used instead of ordinary sugar for tea, coffee, and the like. Compotes of stewed fruit may be sweetened by it, and such a compote taken once a day at least. A very good combination is two parts of prunes and one of figs. Raw fruit I do not approve of. Huckleberries and cranberries are to be strenuously avoided. Diluted condensed milk may be used in place of ordinary milk.

Passing to liquids we have buttermilk, kumyss, and cider. Buttermilk is much lauded by German authorities, and has in my experience proved very reliable. To secure good effects three glasses should be taken daily. Kumyss has a similar effect, somewhat increased by the stimulating effect of CO_2 on gastric and intestinal peristalsis. Kefir is not obtainable in our markets. White wines may be allowed in moderation.

Fats are indicated in large quantities but their administration is somewhat difficult. The simplest form is to give butter, $\frac{1}{8}$ to $\frac{1}{4}$ pound daily. Cream seldom agrees. Cooked fats are of course injurious. In debilitated subjects cod-liver oil may be an excellent adjuvant. In young subjects the addition of fat to the diet may alone be sufficient.

Measures strengthening the abdominal wall consists of (1) massage, (2) abdominal gymnastics, (3) electricity, and (4) abdominal supports. Except in cases where constipation was dependent upon a neurasthenia, for which latter condition, general, not local massage proved of value, *massage* has been disappointing. This may be contrary to the general impression but after extended and repeated trials I have abandoned a large measure of my previous hope in its efficacy. If ordered it should be given by an experienced operator. Massage is contraindicated in all inflammatory and spastic conditions.

Abdominal gymnastics are more serviceable. General exercise, especially bicycling and golf, are of great service, together with local exercises, such as the raising of the leg slowly to the vertical position and dropping it to the bed again.

Electricity has been to me a grievous disappointment. I have used faradism in a variety of ways, usually one broad electrode over the umbilicus, a smaller one to the left of the spine at the level of the twelfth dorsal vertebra, but I have never been convinced of its utility. The results, however, are so good in atonic conditions of the stomach, that I still continue hoping better things from it in intestinal work. Of galvanism I have not sufficient knowledge to speak. Lately, Boas has had great success in rectal faradism. One pole being inserted into the rectum, the other, flat electrode, is to be placed at various points over the colon. Boas claims brilliant success, and as he is a most conservative observer, great weight must be attached to his statements.

Artificial abdominal supports are indicated (1) in downward displacements of the stomach or colon; (2) in weakness of the abdominal wall or separation of the recti muscles. The supporter should always be adjusted before rising in the morning and worn continuously through the day. The most convenient apparatus is the Bardenhauer, made by the Pomeroy Truss Company, Fifteenth street and Broadway, from the original Bardenhauer. (I do not know of any other place where they can be obtained.) In these cases the patient should be instructed to suspend the

clothing from a corset-waist and not from the waist.

III. Hydrotherapy is a measure which must not be lightly passed over. The glass of cold water on rising has a well-known effect upon intestinal peristalsis, but its disadvantage is that it exerts a depressing effect upon gastric secretion.

The spinal douche I can strongly recommend. While the patient sits in as hot water as can be borne, the spine is at first sponged with hot water, after which a pitcher of cold water is poured from a considerable height upon the back. Brisk friction should follow, and the hour of selection should be before breakfast. When the spinal douche cannot be given the patient may stand before two basins, one of hot and one of cold water, and alternately sponge the abdomen with the hot and cold. Such treatment is serviceable in atonic forms of constipation, but is contraindicated in inflammatory and spastic conditions.

IV. Sedative remedies are indicated in conditions of intestinal spasm, a more frequent class of cases than is ordinarily supposed. In this type, purgatives, massage, and bulky articles of diet are to be excluded, and a more soothing régime inaugurated. Attention should be paid to the primary cause, usually a hyperacidity of gastric contents. An efficient remedy in these cases, about which I can speak from considerable experience, is the Priessnitz Umschlag or Neptune Girdle. Two thicknesses of flannel, large enough to cover the abdomen, are wrung out in hot water, covered by oiled silk, and applied to the abdomen at night by means of a binder. The soothing effect of a nocturnal hot bath is often of service. Small doses of sodium bromid and belladonna, preferably with chloroform-water as a vehicle, may be necessary in obstinate cases.

V. Oil irrigations were first employed by Kussmaul, and are generally known by his name in German literature. The results personally seen in Boas' clinic and in my own practice have been so brilliant that I am inclined to attach much importance to this form of treatment. A rectal tube of large caliber, with a large lateral opening, is introduced six to eight inches into the rectum, and from six to eight ounces of a bland oil slowly allowed to enter. Cotton-seed oil free from rancid acidity, is as satisfactory as olive oil, and is inexpensive. In Boas' and in Pick's clinics, the patient assumes the knee-chest position. My modification of this is more agreeable to sensitive patients.

The patient receives the injection while in the Sims' position, with the hips elevated on two pillows, and with the muscles well relaxed, remains so placed for ten minutes, then the dorsal decubitus is assumed for ten minutes, after which the patient lies for ten minutes on the right side, the hips still being elevated. By this method the oil reaches throughout the entire length of the colon. No immediate results occur, as a rule, and the patient may go about his daily work, although the injection is to be given by preference at bedtime. In the great majority of instances the patient will have one normal movement for three to five successive mornings without straining. The action of the oil seems to me to be due to the fact that the intimate commingling of the oil with the feces prevents all further drying processes, thus markedly facilitating the outward passage of the feces, and in presenting a greater bulk to the expulsive efforts of the rectum. Pick recommends daily inspection of the stools and a repetition of the injection whenever the oil disappears from the feces. It is just as well, however, to rely upon clinical data, and to repeat the treatment whenever the effects of the previous injection have subsided. Ordinarily, every five days is sufficient. One great advantage of this method is that it may be used in atonic, spastic, and inflammatory conditions alike.

A successful case of treatment by the oil method is hereby attached.

Miss C. E., forty-eight years of age, for thirty-two years had never known a natural desire for stool. By enormous doses of laxatives, supplemented by glycerin injections, the bowels had been made to move, but without these remedies no natural action would occur under seven to fourteen days and then only by repeated straining efforts. Appetite was practically nil. For three years she has been constantly under medical advice for her constipation. For three years had abdominal massage daily without relief. Seen March 10, 1898. She was spare and under-nourished. The lower border of the stomach reached two inches below the umbilicus, and loud splashing sounds elicited during the fasting condition betokened an advanced degree of muscular insufficiency.

The abdominal wall was of normal strength. The rectum was normal, but a moderate impaction could be felt in the sigmoid flexure. Upon irrigating the colon a normal quantity of neutral-saline solution could be introduced and was expelled with normal involuntary force. No mucus was evident in the washings. Inflation showed the colon somewhat dilated and the transverse portion sagging down in the median line, the so-called M shaped colon. Chemical examination of a Boas-Ewald test-breakfast revealed normal digestion. No other abnormalities were detected. March 11th the irrigations were begun and have been repeated every five days since that date. Since the first injection she has never missed a single day having a perfectly natural and sufficient stool, with normal desire, after breakfast. She has not had during this time a single laxative drug.

The adjuvants to treatment consisted of honey and

milk in the morning, two glasses of buttermilk daily, although often for days in succession she would omit this, and a Bardenhauer belt. Her general condition is wonderfully improved and in all respects she considers herself a well woman.

If a colitis can be excluded, either atony or spasm probably exists. Atony is shown by the facility of the entrance of water into the gut and diminished involuntary efforts to expel it. In addition small quantities, less than one-half pint, allow of loud succussion sounds by abdominal palpation. Here all the constipation-diet may be used together with massage, electricity, douches, and the oil irrigation.

Spasm is detected by the difficulty experienced in introducing a normal amount of infusion and the violence of its involuntary expulsion. In this form the symptoms are, moreover, intermittent and the gut often experiences cramp-like pains without successful stool, often after the taking of food or after nerve exhaustion. Here the bulky foods, massage, electricity, and cold douches are contraindicated, while a more soothing régime, previously alluded to, is followed by good results. In these cases a condition of gastric hyperacidity is often a reflex cause. Sodium bicarbonate after meals will settle this point beyond dispute. Careful examination of the rectum should also be made for hemorrhoids, catarrhal proctitis, rectal ulcers, strictures, or fissure, as any rectal inflammation may lead to reflex intestinal spasm and constipation.

In conclusion, the writer desires to emphasize the importance of a careful physical examination, if good results are to follow the treatment. A cough should no more be treated by empiric methods alone than should constipation; both are symptoms, denoting predisposing and exciting factors, and the determination of these must precede a successful therapeusis. Negligent habits must be corrected, the nervous expenditure and nervous income must at least be balanced, and in almost every case a physical examination of the colon should be made. A convenient morning scheme for examination and indications for treatment which I can personally recommend, is as follows: The colon is flushed out with normal salt solution, and the wash-water examined. If mucus be present, pointing to an intestinal catarrh (excluding nervous forms of membranous colitis), bulky forms of food are to be excluded from the constipation-diet, massage, electricity, and cold abdominal applications are contraindicated, but irrigations may be used with benefit. Abnormalities in the position of the colon can be easily appreciated by inflation with air, and call for the Bardenhauer or similar abdominal support. The patient should, moreover, be instructed to lie down at least one hour in the middle of the day. Other measures calculated to strengthen the abdominal wall are also indicated.

The writer firmly believes, as the result of his experience, that careful and systematic treatment along the lines indicated in this paper will be followed by successful and more or less permanent results in the very large majority of patients. There may be a small percentage of such advanced cases as will require in addition some medicinal laxative, but such a percentage the writer believes to be a trifling one. Certainly within the past two years such a one has not come to his notice.

A CONTRIBUTION TO THE SUBJECT OF THE SERUM-TEST IN THE DIAGNOSIS OF TYPHOID FEVER.[1]

BY GEORGE H. WEAVER, M.D.,
OF CHICAGO;
ASSISTANT PROFESSOR OF PATHOLOGY IN RUSH MEDICAL COLLEGE.

IT is not the object of this paper to discuss the history of, or to review the literature bearing upon the subject of, serum-diagnosis. It is sufficient to say that the test is the direct result of a long series of scientific investigations, for the prosecution of which we are primarily indebted to R. Pfeiffer, and also to Kolle, Loeffler and Abel, Sobernheim, Gruber, Durham, Widal, and others. I desire to add the results of some observations which were made during February, March, and April, 1897, and reference will be made to special articles only as bearing upon particular points under discussion. I will not describe the different methods employed by various workers since the underlying principles are the same in all, although there may be differences in the details of their application.

The phenomena upon which the test depends may be briefly described as follows: If a drop of blood-serum from a healthy person be mixed with a drop of water in which typhoid bacilli are suspended, and the drop of the mixture thus prepared be examined under a high-power objective, the bacilli will be observed to lose more or less completely their power of motion and to collect in larger or smaller clumps. If instead of pure serum we employ serum diluted with water in varying proportions, the effects upon the bacilli become less as the serum becomes more dilute and when only one part of serum is present in thirty to forty of water, the bacilli remain very active and show no tendency to collect in clumps. If the same observation be made with blood-serum from patients ill with typhoid fever the effects upon the typhoid bacilli will not be identical, but will differ in degree rather than in kind. The

[1] Read before the Illinois State Medical Society.

so-called "reaction," *i.e.*, loss of motion and clumping, is observed as in the case in which normal serum is used, but it occurs when the dilution of the serum is carried to a much higher degree. It is generally true that such a reaction occurs in dilutions of typhoid serum above 1 to 40, and does not occur in dilutions of the serum of persons in health or of those suffering from other diseases above that point.

In most of the published communications, the writer simply reports the presence or absence of the "reaction" in a series of cases. It is very evident that the term does not signify the same in all cases. One writer follows the original suggestion of Widal and considers a reaction for typhoid to be present when serum diluted ten times causes a clumping and loss of motion after thirty minutes; others where the same occurs in about the same time if the serum is diluted thirty or forty times; and still others would extend the time of observation to several hours. Very few observers have made any definite statements regarding the virulence of cultures, which is known to become less when the bacilli are grown upon artificial media. It is, however, probable that most of the observers have reached definite conclusions as to what constitutes a reaction by their personal experience with the particular cultures employed by them. If these details were given in each instance, the value of the report as an aid and guide to others would be much enhanced, while now many of them are of little or no value.

In the tests which are here reported four different cultures of typhoid bacilli were used, and will be designated as Nos. 1, 2, 3, and 4. No. 1 was obtained from the spleen of a patient who died of typhoid fever six months before using. No. 3 was an old laboratory culture, having been grown upon artificial media for sixteen months. Nos. 2 and 4 were isolated a few days before being used from the spleens of patients dead from typhoid fever. All conformed perfectly to the typhoid bacillus in their

morphology and cultural peculiarities. Nos. 1 and 3 were therefore of a lower degree of virulence than the others.

The examinations were made as follows: The blood was obtained from a prick in the end of the finger or lobe of the ear, the surface having been previously thoroughly washed with alcohol. It was collected in a small, sterile U-shaped glass tube, and also a couple of drops were placed upon a clean glass slide and allowed to dry. By means of a centrifugal machine the serum in the tubes was separated from the rest of the blood. The tube was then cut off at the lower part of the layers of serum, and the serum blown out into the cell of a sterile hollow-ground slide. When the serum was diluted, this was done by means of fine, graduated, sterile glass tubes, bouillon being used as a diluent. A culture of typhoid bacilli which had grown upon rather dry agar-agar for not more than twenty-four hours at 37° C. was used. As much of such a growth as could be carried in an ordinary loop of a platinum needle was thoroughly mixed in 1 c.c. of bouillon. A hanging drop of this was examined to determine whether the bacilli were actively motile and not in bunches. Upon a cover-glass, sterilized in a flame, a drop of this emulsion of bacilli was mixed with a corresponding drop of the strong or diluted serum to be examined, the cover-slip then being inverted and placed over the concavity of a hollow-ground slide and sealed with vaselin. When the dry blood was to be examined, a drop of bouillon was placed upon the dry blood and after some of the serum had been dissolved, it was used in the same way as the fresh serum. The hanging drops thus prepared were examined with a No. 7 Leitz objective and No. 3 eyepiece. The observations were made for various lengths of time up to three or four hours at room temperature, and after keeping the slides at 37° C. from sixteen to twenty hours.

CHART I.—I will first call attention to the results obtained in the examination of blood from nine healthy persons. The tests were here made with fresh serum only, and parallel observations were made with cultures of different degrees of virulence. From the accompanying chart it will be seen that in the case of the strong serum, after forty minutes at 20° C., the bacilli were sluggishly or not at all motile, and showed slight or no clumping. As the serum was diluted in increasing degrees the effects upon the bacilli became less until at 1 to 40 there was produced no effect upon the motion and no clumping either in forty minutes at 20° C., or after sixteen hours at 37° C. It will will also be noticed that in the preparations made from strong serum, after keeping for sixteen hours at 37° C., there was little or no clumping, and active, or sluggish motion. The

clumping and the effects upon motion were more marked in the case of the slightly virulent cultures and manifested at greater degrees of dilution of the sera. These results correspond with those obtained by several observers.

CHART II.—Thirty specimens of blood from persons with diseases other than typhoid fever were tested. In most of them fresh serum and dried blood, collected at the same time, were used. The results are given in the chart as positive (+), negative (—), and doubtful (?). In all, the results were arrived at by the following method: Culture No. 1, which was non-virulent, or of a low degree of virulence, was used in the preparations together with the strong serum or strong solution of dry blood. The slides were kept at 37° C., 98° F., for sixteen to twenty hours, and then examined. Those in which no motion was present were marked positive, whether clumping was marked or absent. Those were marked doubtful in which such a preparation showed some motion, and more or less clumping. The negative results were recorded where the bacilli remained actively motile and showed no clumping. It will be noticed that in no case of this series was a positive result obtained, and in only few a doubtful one (four with fresh serum, and six with dry blood). The doubtful reactions were slightly more numerous when dry blood was used.

CHART III.—Thirty-two cases of typhoid fever were tested in the same manner, and the results indicated in the chart are estimated upon the same basis as the series given above of non-typhoids. Of thirty cases tested with fresh serum, three only gave a doubtful reaction, all the rest being positive. All of the doubtful cases were fatal. Two patients (twenty-third and twenty-sixth) at autopsy showed only typical lesions of typhoid fever. The other patient (twenty-fifth) at autopsy presented, in addition to typical typhoid lesions, also tubercular lesions in the lungs. In each of these cases only a single specimen of blood was examined. Two other specimens collected at the same time as these three and tested with the same emulsion of bacilli gave positive results. The degree of reaction with dry blood from these three fatal cases was less than with fresh serum, in two the result being entirely negative. Of twenty-nine cases in which the test was made with dry blood, nineteen gave a positive, eight a doubtful, and two a negative reaction. In one of those counted as giving a positive reaction, it was obtained only upon a second examination. From the chart it will be seen that a negative or doubtful re-

sult was obtained in some cases in which the fresh serum gave a positive one. In a few cases dry blood was tested after being kept sixty days, and it still caused the same effects upon the bacilli as when freshly dried. In Case I. of this series, no test was made with fresh serum. The case terminated fatally and the autopsy revealed typical typhoid lesions, with tuberculosis of the lungs. Typhoid bacilli were cultivated from the spleen and gall-bladder which reacted perfectly to the serum from advanced cases of typhoid. Tests made with the serum from the heart obtained at the autopsy gave only a doubtful reaction. In both the cases in which typhoid fever and tuberculosis were demonstrated by the post-mortem examination to be present the reaction was doubtful. This result is different from that obtained by Zienke[1], who found a positive reaction in a fatal case of typhoid and tubercular infection.

In the first cases examined observations were made of the preparations when kept at room temperature for thirty minutes, but while in many there was clumping and complete loss of motion when the serum was diluted fifteen times, in other cases of undoubted typhoid fever, slight motion remained, even where with strong serum after sixteen hours at 37° C. motion was entirely lost. On account of the impossibility of deciding on such reactions this method was not extended to all the cases.

Two specimens of serum were tested where the person had had an attack of typhoid fever some time previously, and had since been in good health. In one case where the attack had been six years before, the reaction differed in no way from that in other healthy individuals. In the other case in which the attack had been passed through about a year previously, the reaction was doubtful according to the standard given above. In the fresh serum, clumping was well marked but motion remained quite active in a dilution of sixty times after thirty minutes at room temperature.

In many of the cases of typhoid fever tests were made with the same specimen of serum, using different cultures. In general, the clumping was more prompt and the interference with motion more pronounced when the less virulent cultures were employed. In some cases the strong typhoid serum after sixteen hours at 37° C. failed to cause a complete loss of motion of the more virulent cultures, a few isolated bacilli remaining sluggishly motile. This corresponds with the observations of Kolle[2], and others. In the hanging drops made with strong serum, there was a considerable increase in the number of bacilli when kept for several hours at 37° C.

The results obtained by these examinations may be briefly stated. A complete loss of motion after keeping a preparation, made with strong serum and a non-virulent, old culture, for sixteen to twenty hours at 37° C. was only observed in cases of typhoid fever. The presence of such a reaction would indicate the presence of that disease. In occasional cases of typhoid fever, even late in the disease, such a reaction is not obtained. Its absence cannot, therefore, be accepted as excluding the diagnosis of typhoid in a given case in the presence of other signs of the disease. The same statements may be made regarding strong solutions of dry blood employed in the same way. This and other methods of using the test will give slightly different results if cultures which are virulent be employed, and the results must be judged accordingly. The ability to cause clumping and lessened motion of typhoid bacilli is not peculiar to the serum from cases of typhoid, and varies in degree in different cases of typhoid fever. In the earlier stages of the disease and occasionally late in its course, the effect produced may not exceed that caused by serum of corresponding strength from healthy persons or from those sick with other diseases. Whatever method is employed, with the possible exception of that in which large quantities of material are examined in test-tubes, it does not seem possible to place all cases in either the positive or negative group. Beside those which may be classed with a considerable degree of accuracy, there remains a considerable number of cases which must be placed in a group giving doubtful reactions. This has been insisted upon by Brannan,[3] Kolle, Ziemke, and Jez.[4] These cases may or may not be typhoid fever, the diagnosis resting upon the other signs of the disease.

Dry blood gives less accurate results than fresh serum, and is to be used only when fresh serum cannot be obtained. It is very difficult or impossible to get serum of a definite strength from it.

In conclusion, it is my pleasant duty to thank Drs. J. B. Herrick, A. R. Edwards, and G. F. Butler for their kindness in allowing me the use of the abundant material in their wards in the Cook County Hospital, and the members of the resident medical staff for many favors extended me during the carrying out of these observations. The diagnoses have been accepted as made by the medical men in charge of the patients, and have not been influenced by the results of the test.

THE PATHOLOGY AND TREATMENT OF ACUTE GONORRHEA IN THE MALE.[1]

By ROBERT W. TAYLOR, M.D.,
OF NEW YORK;
CLINICAL PROFESSOR OF VENEREAL DISEASES IN THE COLLEGE OF PHYSICIANS AND SURGEONS, COLUMBIA UNIVERSITY.

In compliance with the courteous invitation of the president of this Association, I shall present a short and practical survey of the pathology and treatment of acute gonorrhea in the male. Within the last few years so much has been written on this subject in a loose, quackish, and unscientific manner, and such brazen recklessness has been indulged in concerning methods of treatment and alleged wonderful and rapid cures, that the time is ripe for a clear, practical, and conservative discussion of it in all its phases. By the perusal of the various recent sensational papers on the treatment of gonorrhea, one is impressed, first, with the flippancy of tone as to the real nature of gonorrhea; and, second, with the utter lack of appreciation, we may say even ignorance, of the pathology of this virulent, infective process.

When we read that a certain method of treatment is so successful that it fails in less than two per cent. of cases, that sixty per cent. of cases of acute gonorrhea are cured in ten days, thirty per cent. in fourteen days, and that in only two per cent. is a cure postponed in consequence of the carelessness and unwarranted indulgence of the patients, we naturally wonder why it is that we cannot attain such ideal results. Then, when we further see it claimed that eighty-two cases of genuine gonorrhea are cured in three days, that by this miraculous method of treatment anterior urethritis never extends into the posterior urethra, and that the classical complications of gonorrhea are never seen, we marvel at the recklessness of the statements, and sincerely hope that the profession at large will not be influenced by such unsupported assertions. It is most unfortunate that in the treatment of urethral gonorrhea and its sequelæ so many fads and useless innovations are indulged in, so much intemperate medication and manipulation are employed, so much useless and dangerous instrumentation is practised, and in late stages so much unnecessary cutting is done. For the care of urethral troubles, mild, judiciously-applied treatment is especially called for, yet by very many surgeons this delicate canal, the urethra, is dealt with with a heavy hand. Undoubtedly, our more precise knowledge of the pathology of gonorrhea, of its bacterial origin, and of the value and necessity of antiseptic measures have taught us many advances in treatment, still there is much in the older methods which has proved to be beneficial, and which should not be unthinkingly cast aside as out of date.

Fortunately, our knowledge of the gonorrheal process is quite complete, and its symptoms and secretions can now be so intelligently studied that the intimate course of the disease is clearly revealed to us. In the majority of acute cases of gonorrhea the infecting agent is the gonococcus, and in a small minority the infection is produced by staphylococci and streptococci. As a rule, it may be stated that the severe order of cases is produced by the gonococcus (which also may in some instances give rise to mild cases), and that very many subacute cases, particularly in second and late infections, are caused by the ordinary pus-microbes. As regards the acuteness and severity of the attack, much depends upon the potency and quantity of the infecting agent received, and also upon the susceptibility of the tissues of the indvidual. These conditions, namely, the potentiality of the poison and the susceptibility of the individual, are, therefore, the essential causes or factors in the greater or lesser severity, or of the more or less mild character of the attack of gonorrhea. In actual practice we find in cases of acute gonorrhea the most varied gradations of severity and mildness, and that while many cases are very rebellious to proper treatment, others yield more promptly, while in a few a cure is readily produced. It will thus be seen that in order to formulate reliable data as to the value of a method of treatment, the intimate nature of the cases so treated should be clearly understood and stated. It follows, also, from the fact of the marked differences in the character and severity of cases of acute gonorrhea that they require variations and modifications of treatment, and consequently that routine measures are unscientific and unreliable. These facts should always be well borne in mind by the surgeon in reading of the wonderful exploits and claims of the promotors of routine methods for the rapid cure of this disease. It may be confidently affirmed that these stencil-plate schemes of treatment will never be accepted as permanent additions to our therapeutics.

In all probability the gonococci are most commonly conveyed to the infected individual by means of pus-cells, in which they are inclosed, and they may also be transferred in a free state in a mucous or serous secretion. Being sucked from before backward into the urethra by the capillary attraction which exists in that canal, these germs then become diffused over the surface of the mucous membrane of the fossa navicularis, and then, by reason of the susceptibility and fertility of the soil, rapidly

[1] Introductory essay to a general discussion on "Gonorrhea," read before the New York State Medical Association (Fifth District Branch), May 24, 1898.

or slowly increase in numbers. In this stage of microbic colonization, if the gonococci are numerous and virulent, and if the tissue susceptibility is well marked, a short period of time only elapses before the disease is well under way. If, however, the microbe is less potential and the tissues offer resistance to its virulence, the period is more or less prolonged. Now, it has been very clearly demonstrated by microscopic studies of infected mucous membranes and of the secretion obtained within a short time after infection, that at first the gonococcus grows on the superficial layer of the mucous cells, and there it increases in area like a sod. This is the way in which the infecting agent gets a foothold, and when that condition is fully accomplished the inward invasion promptly begins.

Applying these well-demonstrated facts to actual practice, we find the following conditions: the infected individual, one or several days after coitus, may feel a sensation of warmth or of tickling or smarting in the fossa navicularis, and he may observe that the lips of the meatus are slightly glued together or that there is a small drop of clear mucus at the urethral orifice. If the surgeon can catch the case at this time he will find that this secretion, when spread on a glass slide, is clear serum, in which are a few particles of white granular matter, like broken rice or molecules of suet. When properly stained, mounted, and placed under the immersion-lens, the microscopic field shows many epithelial cells, usually of the columnar, and perhaps of the flat, variety. Scattered more or less numerously over the surface of these cells the gonococci are seen, and they also may float free in the serum. At this time there are no pus-cells in the specimen. These clinical and microscopic facts incontestably prove that this infecting agent is yet on the superficies of the mucous membrane, and that the inward invasion, though imminent, has not yet occurred. Here, then, is the opportunity for the abortion of the infection, and if ever cases are cured in a few days it is those in which these conditions exist. If at the time we can so act on the parts that we kill and dislodge the virulent micro-organism, we may abort the impending infection, but if we fail we may only delay the onset of acute symptoms or we may hasten their development. Unfortunately for the human race, men, as a rule, are not sufficiently aware of the gravity and the portent of the seemingly mild and insignificant symptoms of an oncoming gonorrhea, and they rarely consult the surgeon at this important period. The morbid process, therefore, being unchecked, the invasion of the deeper tissues is more or less promptly effected. With the increase in the number of the micro-organisms toxins are produced, which quickly disintegrate the mucous membrane and rend the cells asunder. Then between the cells the gonococci, in Indian-file or in swarms, pass inward, and when they reach the submucous tissue they encounter the blood-vessels, which immediately pour forth vast quantities of leucocytes, which, by phagocytosic action, englobe the microbes, and in a strong current carry them into the urethral canal. The patient then observes that he has a profuse discharge and that he suffers from acute symptoms. The purulent secretion of this florid gonorrhea then shows very clearly marked features. To the eye it is yellowish and of decided thick consistence, and under the microscope it is seen that it is composed of pus-cells, many of which contain gonococci, which also may float free in the serum. Having gained a hold in the region of the submucous tissues, this micro-organism then produces a very severe exudative inflammation, attended by the profuse development of small, round cells. Thus we have acute microbic invasion with the destruction of the superficial layers of epithelium, more or less disintegration of the membrane attacked, great irritation and hyperemia of the vessels and much cellular exudation. This constitutes acute gonorrhea. In the majority of cases the infective process promptly travels backward as far as the bulb, where it may stop, but as a rule it creeps onward and involves the posterior urethra.

Gonorrheal inflammation is peculiarly prone to remain active, and by its persistency the submucous exudation is much increased, and a catarrhal condition of the mucous membrane is produced. We, therefore, have to treat a mucous membrane which is more or less damaged, a submucous tissue from which we must cause the absorption of tissue exudates, and dilated and inflamed vessels which have lost their normal tonicity. In addition, while we are causing the tissues to heal, we must so act upon the gonococcus that its virulence is destroyed, and then it withers and dies. It will be seen that in the list of requirements necessary for a cure I have placed the killing of the gonococci last, and I do so with a purpose. Too much stress is thoughtlessly laid upon the virulence of this microbe to the exclusion of the pathological condition which it produces. While we may use in moderation antiseptic agents, our aim should always be to allay and cure the inflammation of the tissues, for that is the morbid condition in which the microbe finds nutrient soil, and in it it luxuriates. Therefore, when we cure the inflammation the microbe dies of inertia and famine, its death being produced by indirect means.

The scheme of most of the new quick-cure treatments consists in the irrigation of the urethra with

some antiseptic solution, chiefly of permanganate of potassa, and also of bichlorid of mercury. The most blatantly advertised treatment of gonorrhea, known as the method of Janet, is essentially based on the fact that, as a result of a certain technic, the posterior urethra and the bladder can be injected from the meatus without the aid of a catheter. It is assumed that the catheter may not only act as an irritant, but that it is a fruitful source of infection. Janet uses an irrigator or a fountain-syringe, to which is attached about six feet of India-rubber tubing of 30 F. caliber. Into the distal end of this tube a goodly-sized conical glass nozzle is inserted, while an India-rubber stop-cock completes the apparatus. The reservoir for the injection, whatever it may be, is elevated above the patient about two feet, when the anterior urethra only is irrigated, and about four and a half feet when the posterior urethra and bladder are medicated. The patient, after urination, is placed on his back, and the conical nozzle is well, but not forcibly, introduced into the meatus; then the current is allowed to flow. The therapeutic agent employed by Janet and his followers is permanganate of potassa dissolved in warm water. The solutions vary in strength from 1:10000 of water to 1:4000. Toward the end of the treatment, with the decline of the acute symptoms, the strength may be 1:5000. For the irrigation of the anterior urethra about one pint of injection may be used, while for the bladder two lavages or irrigations of about a pint each may be introduced.

By this treatment Janet claims that he not only aborts incipient gonorrhea, but promptly cures cases in the acute purulent stage. This treatment of Janet must, of necessity, be administered by the surgeon, to whom the patient must go once, or perhaps twice, a day, morning and evening.

This treatment, and other similar ones, certainly cut short the severe symptoms in many cases, and quite promptly cause the purulent discharge to become mucopurulent. These results are then paraded as astonishing, and cases presenting them are looked upon as having been cured. When these enthusiasts are asked in what a cure consists, they reply: "There may be some little redness of the mucous membrane left and a little sticky discharge, but the patient is all right." It is hard to understand how intelligent men can thus deceive themselves. Many patients thus treated, knowing little of gonorrhea, consider themselves cured; others see that they are really not cured, and they disappear, and their cases are registered on the books as cured. Then, again, in this sticky condition antiblennorrhagics and the usual astringents are very often used to complete the cure, but if they are successful the credit is given to the heroic remedy which calmed inflammation and more or less rapidly changed the character of the discharge.

In the majority of these cases there can be no doubt the patients are not in any sense cured. They have been rapidly pushed into the terminal stage, which in very many cases has no end. Now, if we study these cases carefully (as, so unhappily, it is our frequent duty to do) in the light of the pathology of the gonorrheal process and of their pathological course, we see that the treatment has caused a much greater exudative inflammation into the submucous connective tissue than is seen in cases temperately treated, and that the catarrhal inflammation has been brought down from free suppuration to the production of a thick mucopurulent secretion. This is shown in the earlier times by the decidedly full, tense, and thickened condition of the pendulous and subpudic urethra, and by the examination of the urine, which, strange to say, is not insisted upon by the authors of these rapid-transit treatments, as they are called. Then the patients, if they have escaped epididymitis, have symptoms of posterior urethritis, urethro-cystitis, and often bladder incompetence, and more or less incontinence. They often, further, suffer from urine-dribbling, which is due to the infiltration into the urethra walls, which prevents the canal from performing the final expulsive acts of urination. As time goes on this exudative process, which involves nearly, if not all, of the anterior urethra, and perhaps the posterior part also, produces connective tissue, and as a result the canal is more and more constricted, until in some very bad cases a condition bordering on stenosis is left, accompanied by all the distressing conditions incident to the blockade of the bladder. This picture is not one particle overdrawn, but is based on the unbiased study of many cases of acute gonorrhea which have been railroaded into the terminal stage.

It may be claimed by those who advocate this form of treatment that they never see these results. Perhaps they fail to appreciate the deplorable condition the patients are left in, but as a rule these same patients think that they have had enough of that sort of treatment, and they have sense enough to go elsewhere. It follows, therefore, that a treatment which is at once sufficiently active, but conservative and based on a knowledge of the pathology and course of gonorrhea, is the one which in the end will give the best results and spare the patients much trouble and suffering, and perhaps permanent infirmities.

The enthusiasts of the new methods in gonorrheic therapeutics are so wedded to their one manipulation, namely, the hydrostatic irrigation with per-

manganate of potassa, that they pay no heed to the general care of accessory symptoms. So long as they are firing heavy charges of their favorite antiseptic against the gonococcus there is no need to do more. That is the alpha and omega of their creed. Now, this irrigation treatment, which has been experimented with in America for about fifteen years (long before this Janet irruption broke out), is worthy of serious consideration, and it is unfortunate that the method has been exploited mainly by enthusiasts and theorists, who have indulged in it as a fad or a hobby.

Seeing that gonorrhea is a virulent process set up by the gonococcus, it is evident that if we can do so without increasing inflammation, we should act directly upon the parts attacked. The trouble with the so-called advanced therapeutists is in two directions: First, they have been so carried away with their antiseptic gonococcide agent and procedure that they have shut their eyes to the old and tried means of symptomatic alleviation; and, secondly, by the vigor of their hydrostatic attack upon the microbe they intensify and cause to extend more deeply the submucous cellular infiltration incident to gonorrhea, and so impair or damage the resiliency of the parts (urethral musculature and compressor urethræ muscle) that they loose their tonus. They also very frequently produce chronic prostatic congestion, which shows a great tendency to remain, uninfluenced by proper treatment.

These statements are in no way overdrawn, since they are the result of extended personal observations and of many competent and unprejudiced men. What should be a boon to the human race is converted into a curse by reason of the unnecessary heroic and incessant manipulation incident to the method. It is true, nevertheless, that infinite benefit will result from careful conservative local medication, even in acute gonorrhea, and that it is time now to make more effort than we did in former years to mitigate and abridge the course of this affection, and I think I can show how this can be done in a simple, safe, and conservative manner.

Treatment.—If gonorrhea can ever be aborted it is in the stage of microbic colonization before the inward invasion has begun. At this time injections given by means of a soft-rubber catheter, 12 French scale, cut to a length of three and a half inches, which will reach just beyond the fossa navicularis, may sometimes kill and dislodge the microbe. The antiseptic solutions should be rather strong, and composed of either potassa permanganate, 1 to 500 or 1000; nitrate of silver, 1 to 250–500, or of the bichlorid of mercury, 1 to 1000 or 2000. Two or three daily injections of about two ounces of these solutions should be made, and, the patient being at rest, the penis in the intervals should be enveloped continuously in cold dressings. Another rather more energetic abortive method is to introduce the shortest India-rubber endoscope (two and one-half inches long) down the canal just beyond the fossa navicularis, then remove the obturator, and pass down on an applicator a tuft of absorbent cotton sufficiently large to fully and gently distend the canal, soaked in a solution of nitrate of silver (gr. xxx to ℥ i), which extends just beyond the tube, which latter is then to be very slowly withdrawn. In this way a very decided antiseptic and astringent action is produced. The parts then should be injected every two hours with lead and opium wash, and cooling dressings should be applied to the penis.

Even with all the care in diagnosis and the promptness and vigor of this treatment, we can never positively say that it will be curative. By these means I have aborted gonorrhea in some cases, but I am free to confess that I have failed in many others. It is good practice, however, when cases are seen in the very early serous stage to endeavor to abort them in the manner just detailed.

In the treatment of acute gonorrhea at the earliest days of onset it is well to employ the old-time measures, namely, to keep the patient, if possible, at rest; to allow a spare diet; to avoid coffee, spices, liquors, highly seasoned dishes, and asparagus; to administer alkalies with hyoscyamus; to prescribe moderate purgation, and in general to follow an antiphlogistic course. No treatment is rational which does not include these wise and salutary measures.

Now, in the florid stage of gonorrhea, with its profuse yellowish and perhaps bloody discharge, coming from a very highly inflamed and swollen mucous membrane, it becomes a nice question whether one can apply local medication. In very severe cases for the first few days it is best to soak the penis every few hours in hot, concentrated boric-acid water, and perhaps by means of a penis syringe, having a soft-rubber nozzle, to gently inject one or two ounces of this fluid into the anterior urethra. As a rule, this treatment alleviates the patient's sufferings and lessens the inflammation. With the onset of amelioration, which usually occurs in a few days, we can adopt a more radical local treatment. To this end we introduce as far as the bulb the soft and compressible, bulbous-ended Mitchell's reflux catheter, which can be gently passed, without discomfort or any damage, down to the bulb, and through it we can slowly throw 2, 4, or 6 ounces of the warm boric solution, which returns and drops out of the meatus. As a result of these procedures the patient becomes much more comfortable, and

there is a perceptible improvement in the urethral inflammation. When this subsidence of the very acute stage is noted, we can go a step further with our local applications. Thus we may replace the boric solution with warm lead-water, or we may use a warm solution of permanganate of potassa, not stronger than 1 to 4000. Under these mild graduated antiseptic measures, as a rule, much improvement will be produced. If, as so often happens, even when care and prudence are exercised, the posterior urethra becomes attacked, it may be well to employ the ordinary velvet-eyed catheter (using very small ones, 10 to 12 of French scale), and to inject some of the fluid into the posterior urethra, and then, withdrawing the eye of the instrument just outside the triangular ligament, to well irrigate the anterior urethra. This mild, carefully-applied, local medication reduces the acute inflammation, and in that way renders the tissues less susceptible to the action of the micro-organism; then as the treatment is carefully kept up the microbes die, since the condition of the tissues is not favorable to their nutrition. When the acute suppuration begins to subside the patient may be instructed to use injections by means of the ordinary penis syringe. Of course, the injections only medicate the anterior urethra, but there can be no doubt that some benefit is produced. The various preparations of zinc, lead, alum, thallin, and hydrastin may form the basis of these injections. In the early florid stage one treatment daily will be required, but with the onset of the terminable stage one every second day will in most cases suffice.

As the inflammation begins to decline it is always well to administer one or more of the old antiblennorrhagics, which, though now frowned upon and discarded by many of the so-called new progressive school, will still, as in the past, prove valuable adjuvant agents in hastening along the reparative process. It is obvious that should these remedies produce, as they sometimes do, gastro-intestinal disorder, their use should be discontinued.

Thus far in the treatment our aim has been to calm and abridge the acute inflammatory process, and to prevent its extension to correlated parts. With the decline of the inflammation a change can be observed by the examination of the urine, particularly that passed in the early morning, which is most important as a guide to subsequent treatment. In the acute and early declining stages of gonorrhea the urine is opaque, and its deposit is almost wholly composed of pus-cells in some of which gonococci are present. With the onset of the reparative stage the microscope shows the discharge to be composed of pus, gonococci and immature epithelium. The presence of these epithelial cells is a harbinger of good import, for they indicate that Nature shows a tendency to repair the damage done and to replace the natural covering of the urethra. In this condition she needs active assistance, and at this time the surgeon can really do valuable work. The pathological indications which at this time present themselves for relief, are: First, to cause the absorption of the round-cell submucous tissue exudation and the restoration of the tonicity of the vessels; and, second, to produce a new epithelial covering for the urethra. Experience shows that the most reliable and effective agent for this purpose is the nitrate of silver. Argonin, argentamin, and protargol are new agents advocated to replace the silver nitrate, but it is yet too early to speak definitely of their places in our therapeutic armamentarium. Nitrate of silver, however, when skilfully used will in general answer all expectations. By its stimulant action this agent causes the absorption of the submucous exudate and constringes the vessels, and by its astringent action it acts powerfully and well on the relaxed and catarrhal mucous membrane, and produces on it a new, and in the end stable, epithelium. When, therefore, the symptoms of the patient and the microscopic appearances of the discharge indicate that the morbid process is about to decline, and this may be as early as the tenth or fourteenth day, or as late as the twentieth of treatment, it is our duty to begin the use of this invaluable agent. If only the anterior urethra is involved, we may use the reflux catheter, but if the totality of the canal has been attacked (as it so frequently is), the 10, 12, or 14 French velvet-eyed catheter should be employed. At first an irrigation of about 2 or 4 ounces of a warm solution of nitrate of silver, 1 to 10,000 or 8000 may be employed once a day. When the effect is good, as shown by the comfort of the patient and the lessening in the quantity of the pus-cells and increase in the number of epithelial cells in the secretion, the strength of the solution may be increased. As a rule, in most of the favorable cases a solution of 1 to 2000 is quite early reached and is well borne; then, as improvement occurs, the irrigations may be discontinued and injections of a few drops of solution of nitrate of silver (once a day or once every second day) 1 to 1000, 500, and 250, may be thrown into the anterior urethra or into its totality, according to the extent to which it is involved.

Examination of the urine will, as the case progresses toward cure, show that pus gradually disappears; epithelial cells are at first abundant, but then they grow progressively less numerous until they disappear entirely. With the cessation of the process no tissue elements can be seen in the urine when ex-

amined under the microscope, and in a few days the little excess over the normal amount of mucus is lost and a cure is produced. In some cases it may be well to follow the silver-nitrate injections for a few times with solutions of sulphate of zinc and of alum.

The treatment thus detailed is very simple and not at all discomforting to the patient, and with growing experience the surgeon will be much gratified with the excellent and permanent results which are produced. By carefully examining the urine, especially the morning specimen, much light is thrown on the progress of the case, and the indications for the frequency and strength of the silver-nitrate solution may thus be learned. In general, it may be stated as the law that as long as there is much free pus and no epithelium in the specimen the solutions should be of the weaker grades, but that as soon as epithelial cells begin to appear the time is ripe for progressive increase in the strength of these solutions.

If this treatment is carefully carried out the integrity of the mucous membrane is restored and annoying relapses are not suffered from, and it goes without saying that stricture-formation is prevented. Then, again, it is unnecessary to use the antiblennorrhagics so freely and constantly as we did in years gone by, and this is a material gain for the comfort of the patient.

With the use of the small, delicate catheters no damage whatever is done the urethra, and the compressor urethræ muscle is not overtaxed and left in an atonic condition, as it is so frequently by the Janet method. Then, again, all the other distressing and discomforting conditions mentioned early in this essay are avoided.

Lastly, let me say a few words as to the length of time for a cure by the treatment just advocated. I think that the public and the profession are to-day being grossly misled and deceived by men who claim that gonorrhea is cured in three, ten, and perhaps fourteen days. I have seen very many of these so-called cures, and have found them to be failures (in many instances the patients being left in a deplorable and incurable condition), and many surgeons of high standing have informed me that they have had a similar experience. Having studied this subject in an unbiased and painstaking way for over thirty years, and having used all agents and methods of progress, I am firmly convinced that if a man is fully cured of acute gonorrhea in from four to six weeks he is a really lucky individual. On the other hand, I well know how readily many late urethral suppurations are cured, and I am firmly convinced that most of the extraordinary statistics of rapid-transit cures now so constantly and unblushingly paraded are based on the observations of these frequent relapses, which even the second-year student in medicine can cure very promptly.

FAVUS, A CLINICAL STUDY, WITH SPECIAL REFERENCE TO TREATMENT.

BY A. D. MAYER, M.D.,
OF NEW YORK.

FAVUS, until of recent years considered as comparatively rare in this country, has within the last decade shown such a marked increase that at the present time it may be regarded as a rather common affliction—one which should prove a source of anxiety to the profession as well as to the public at large. This rapid multiplication cannot be ascribed, however, to the infectious nature of the disease; it is a result rather of the migration to this country of a class of immigrants among whom the affection is very prevalent, namely, the Austrian, Hungarian, and Russian element. Favus continues to be a rare dermatosis among the strictly American population, although occasional cases present themselves.

In the skin service of Dr. C. W. Allen, at the Good Samaritan Dispensary, there were 100 instances of favus, 85 males and 15 females, among 3350 dermatological cases treated from April 1 to December 31, 1897. It should, perhaps, be stated that this ratio is much larger than would be found in other city dispensaries, and is undoubtedly a result of the location in a district and among a people in whom favus is prevalent.

The disease usually begins in childhood, and is most common between the ages of eight and fourteen years. Our youngest patient was but one and one-half years of age, the oldest a woman of fifty. But few of the cases seen developed in this country and most of them were of several years' standing. Filth and overcrowding are the *achorion's* strongest allies, hygiene and cleanliness its most deadly foes.

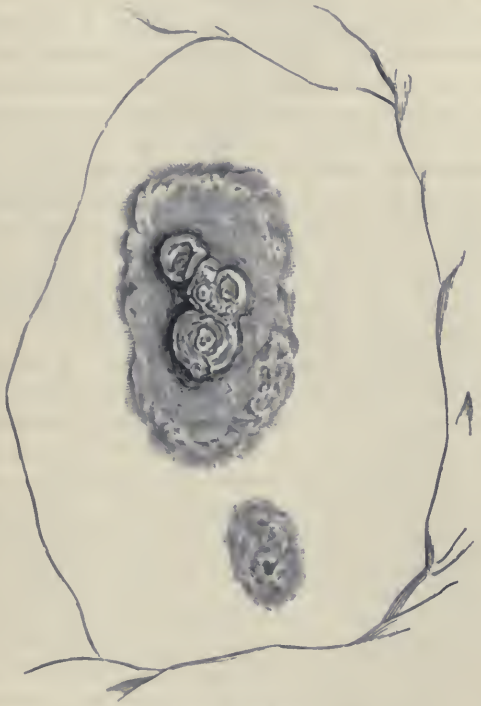
The diagnosis is not difficult in a typical case or in one that has not recently been treated. One would instantly make a correct diagnosis if the scalp were honeycombed with sulphur-yellow, cup-shaped crusts pierced by one or more hairs, the hairs themselves dry, friable, ash-gray, and lusterless, and if patches of alopecia, with their shiny, parchment-like skin were present.

For comparison let us take another case such as is more frequently presented. The mother probably with a view to testing our diagnostic ability, kindly oils and scrubs the head of her child before bringing it to us; in consequence we see only a few small areas of baldness and a diseased scalp which might readily be taken for impetigo, pediculous dermatitis, trychophytosis, or favus. Here, in order to obtain a better view of the head, it is important that the hair be clipped; in fact it is frequently necessary to expose the entire scalp in order to arrive at a diagnosis from the clinical picture alone. If then we see a dry scalp studded with small, red, circumscribed, and irritated, circular depressions, covered by a delicate shining epidermis, patches of cicatrization and alopecia, and perhaps a few cup-shaped crusts, we will not be at a

loss for a diagnosis. If one of these crusts be removed with care we find beneath it a delicate shining epidermal film covering the depression, or if this has been destroyed, we see a glazed, oozing, slightly depressed surface. The yellow crusts are said to have a peculiar mouse-like odor, but I have been unable to verify this in the cases I have seen.

Favus, especially in the early stage, is chiefly to be

FIG. 1.



Favus of the skin.

differentiated from ringworm. In both the hairs are dry and lusterless, but in the latter they are brittle and fracture easily. When this fracture is only partial the hairs appear to be curved, irregular, or twisted. On account of their loss of elasticity any attempt to bend the hairs causes a partial breakage. In epilating, the shaft usually breaks leaving a small projecting stump behind, while in favus, the entire shaft and bulb come away, and we find the hair-shaft split rather than broken.

In many cases the microscope must decide the diagnosis, yet when we investigate the literature on this subject we find very meager descriptions of the differential characters of the microsporon and the *achorion Schoenleinii;* in fact not many years ago they were considered by many, varieties of the same fungus.

In preparing a specimen for examination a portion of the sulphur-yellow crust and a few hairs from the center of a patch should be selected and spread on a glass slide; a few drops of a 10-per-cent. solution of liquor potassæ are added, and in about five minutes the specimen is ready for examination The potassa is absorbed with a piece of blotting-paper and a drop or two of glycerin added before putting on the cover-glass.

The lens employed should have a magnifying power of from four hundred and fifty to nine-hundred diameters. The crust is seen to be composed almost entirely of fungus elements. The *achorion Schoenleinii* is a fungus growth presenting an intricate network of mycelial threads of varying caliber, some fine, others coarse, on the walls and in the meshes of which are multitudes of spores of manifold form. The individual mycelia are segmented at short intervals, form numerous branches and ramifications, and are found within and outside the hair. The conidia vary in size from 2.5 to 5 μ and differ considerably in shape; some are round, others oval, angular, kidney-or biscuit-shaped, nucleated or non-nucleated. The large-spore tinea, or trychophyton megalosporon, with its broad (2 to 4 μ) mycelia and large, round, highly refractile spores (4 to 6 μ in diameter) can hardly be mistaken for favus.

The trychophyton microsporon more closely resembles the achorion. Its mycelia are almost transparent, with parallel edges, and are about 2 μ in diameter. They ramify inside and outside the hair, often dividing by fission, and are segmented at regular intervals by septa containing granular bodies and cells. At the bulb the mycelial threads form a fringe, the distal ends of which terminate in mycelial spores, said to be characteristic. The conidia or spores are small, round, or slightly oval in shape (2 to 2.5 μ in diameter), of nearly uniform

FIG. 2.

Hair infiltrated with Achorion Schönleinii.

size, and while occurring within the hair-shaft are most abundant on the outside where they form a mosaic sheath about the hair.

The mycelia of the trychophyton are longer and penetrate the hair-shaft for a greater distance from the root than do those of the achorion. The individual favus mycelium is shorter and not so slender, and is divided

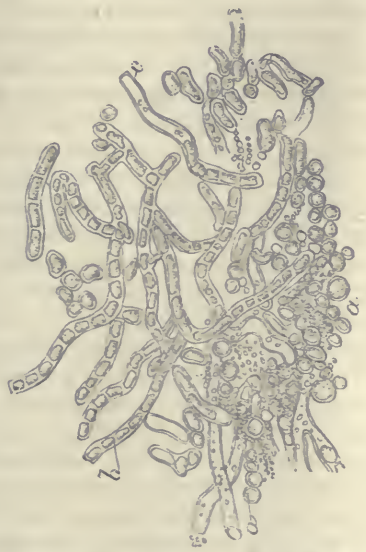
into small segements by very short joints which readily break up into conidia. The latter are cells which spring directly from the mycelial threads, and then become detached; that is, they do not go through the process of fructification.

As stated before, the conidia of the microsporon are of uniform shape, while the favus spores possess multiplicity of form. The largest spore of the former is about 2.5 μ in diameter, or about the size of the smallest of the achorion conidia.

Kaposi says "Trychophyton consists chiefly of long, sparcely branching, moderately broad and uniform mycelia and few conidia." On the other hand, Aldersmith says "Mycelia are seen as minute threads, branching and infinitely ramified, running up beneath the sheath of spores and also in the whole substance of the hair. The broken stump swarms with conidia."

The favus scutulum consists almost entirely of fungus

FIG. 3.



Achorion Schönleinii; (*a*) spores; (*b*) (*c*) sporophores (after Cornish and Ranvier).

elements, while the yellowish crust of ringworm is made up of pus-corpuscles and disentegrated epithelial cells and few fungi.

Favus is an exceedingly obstinate disease to cure. Before beginning treatment the patient, or his parent, should be informed that several months, perhaps a year or more of constant medication is required for the complete eradication of the disease; and he should be impressed with the necessity of regular attendance.

A child with favus should be isolated, so far as possible, it should sleep alone, and have a separate washbasin, towels, brush, comb, etc. School attendance is, of course, absolutely forbidden. A hair-clipping initiates our treatment. In former years Dr. Allen strenuously opposed the use of clippers for cutting the hair of favus and ringworm subjects, especially in institutions, claiming that the machine could not be properly disinfected, and afforded a nidus for the achorion and thus became a source of reinfection and a means of propagation of the disease. Recently, however, he has introduced a system of dispensary hair-cutting and it is now our practice to clip the hair of all favus subjects with a pair of clippers used exclusively in these cases. Lysol in its pure state is employed as a means for rendering the machine aseptic, and also acts as a good lubricant; by constant immersion in this fluid the instrument remains bright and free from rust, and is always ready for use. After cutting the hair the clipper is thoroughly sterilized in boiling water and when dry replaced in the lysol. Before using, the lysol is washed off in hot running water.

One chief object in cutting the hair is to keep these infectious individuals out of the barber-shop, where they habitually resort without apparent objection on the part of the barber. Legislation has been enacted, at least in this city, to keep these children out of school, but the restriction of hair-cutting, in barber-shops, which is just as important, has been ignored. It seems a pity that these children, of whom there is a large number in this city, should be denied the privilege of a public-school education during the necessarily prolonged period of treatment. The establishment of a public school on the lower East Side, to be attended only by children suffering from favus and ringworm as advocated by Dr. Allen deserves further consideration.

After clipping the hair, if the scalp is crusted and dirty, an oil or ointment is prescribed with which to soften the crusts, which are then removed with tincture of green soap. When the patient returns after a few days with a clean head, a 5-per-cent. chrysarobin ointment is ordered and epilation begun. Patients are furnished with epilation forceps by the dispensary at cost price, and some member of the family is instructed how to properly epilate. We insist that the patient come to the dispensary three times a week under penalty of subsequent treatment being refused. When the reddened patches have been well epilated and the scalp looks fairly clean, what we term "chrysarobin paint" is applied. This is a 10-per-cent. solution in collodion and is applied to the closely clipped scalp with a stiff-haired varnish brush two or three times a week. The paint adheres firmly to the short hair and to the scalp, and thus insures continuous medication, while the use of an ointment is frequently neglected or occasionally totally disregarded by the patient. Another advantage lies in the fact that the chrysarobin cannot be disseminated, and hence does not produce a dermatitis of the neighboring parts or cause eye involvement. Not only do we obtain the beneficent action of the chrysarobin, but the dry collodion, by excluding the air from the underlying structures, in itself probably acts as a germicide, or at least tends to prevent the growth and proliferation of the mycelia and spores, since the favus fungus is aerobic and cannot flourish in the absence of oxygen.

When the diseased area is large or the patches scattered over the entire scalp the "yellow-kid" appearance of the head is an objection, and in private practice might prove an obstacle to the employment of the paint. But in private and among the educated and more cleanly population, treatment as a rule will be resorted

to before the disease has made much progress, so that the patches under treatment can be hidden by healthy hair, and at the same time the diseased hair be kept closely cropped. This is especially true in female subjects.

If we desire to inspect the head at any time before the paint has worn off the collodion crusts may be removed by oil or ether. The underlying scalp always looks smooth, is free from dirt, and the diseased patches are readily recognized. If fresh areas of disease have cropped out the ointment may again be used and epilation practised, to be followed after a week or two by chrysarobin-collodion. When too much inflammatory reaction follows the employment of chrysarobin, it should be discontinued for a few days, and a 10-per-cent. ammoniate-of-mercury ointment substituted.

The duration of treatment depends upon the duration and extent of the disease. Small areas may be cured in a short time, but usually a year or more of persistent treatment is required for the complete eradication of instances that are at all extensive. The conscientious use of the epilation-forceps by the patient at home shortens the treatment and is a great aid to the physician.

CLINICAL MEMORANDUM.

AN EXTERNAL URETHROTOMY, FOLLOWED BY TWO SUPRAPUBIC LITHOTOMIES ON THE SAME PATIENT WITHIN A PERIOD OF NINE YEARS.

By L. E. NEWMAN, M.D.,
of St. Louis, Mo.

It does not often fall to the lot of a surgeon to have to perform three operations as important as the above named upon one individual, but the patient, whose case I am about to report, has been subjected to these and is now well, with every prospect of living out a full three score and ten years. It is a source of extreme regret that I am obliged to confess that I have lost or mislaid the notes of the first two operations, and in consequence I shall have to trust to my memory to supply such points as I cannot obtain either from the patient or from records of St. John's Hospital, at which place all three of the operations were performed.

R. M. C., native of the United States, aged fifty years, by occupation a clerk, came to me from Fort Worth, Texas, in February, 1889, complaining of difficulty in micturition due to stricture of the urethra following gonorrhea, which he had contracted at Richmond during the War of the Rebellion. His condition was truly pitiable, for when I requested him to urinate in my presence he was obliged to let down his trousers and then by stooping over and great straining a few drops of urine escaped from the meatus, but the greater amount passed through numerous fistulous openings in the perineum. The urine was dark and foul-smelling, and the cystitis produced constant vesical tenesmus, which was naturally intensified by the obstruction to the flow. He told me that a few years before he had had an attack of sudden retention of urine, which had resulted in rupture of the urethra and extravasation, with consequent sloughing of the perineal tissues and scrotum, and since that time, as he put it, he had "grown a new bag." My examination revealed a stricture about one inch from the meatus, firm and unyielding, as strictures in that region are apt to be, another, about three and one-half inches down, and a third and more serious one, permitting with great difficulty the passage of a filiform, in the deep urethra.

I proposed an operation, to which he readily consented, and at once sent him to St. John's Hospital. Under chloroform, and ably assisted by the late Dr. F. D. Mooney, Dr. P. Wilson of Dennison, Texas, and several other medical friends, I first performed an internal urethrotomy on the two strictures in the pars pendula with Maisonneuve's instrument; then, putting the patient in the lithotomy position, I performed an external urethrotomy for the deep stricture, thoroughly curetting the fistulæ, of which there were six. I tied the catheter in position and ordered morphin for pain, should it become severe. The subsequent history of this part of the case was practically uneventful, the patient making a complete and uninterrupted recovery and being back at his desk six weeks from the date of the operation.

One year later I saw him and found that he had neglected to use his sound regularly, with the result that the two anterior strictures had contracted to such a degree that I found it necessary to divide them again, which I did with Otis' urethrotome, and warned him that such neglect would undoubtedly result in disaster to him if again repeated. I also prescribed salol on account of the cystitis, and subsequently one of the physicians at his home washed out his bladder with what he said was a solution of silver nitrate, which is possible in view of the pain produced by it. I heard no more from him for more than three years after this last visit and had practically forgotten about the case when in the spring of 1894 I received a letter from him stating that he was in a worse condition than ever, and enclosing a small calculus which he had passed per urethram a day or so before.

He stated that the passage of the stone had given him great pain for many hours and that after voiding it his symptoms had been unrelieved. I might mention, *en passant*, that the very fact of the stone, which was as large as a marrow-fat pea, having passed through the urethra was evidence that the strictures had not greatly contracted and I naturally concluded that the condition with which I had to deal was one of stone in the bladder with its accompanying cystitis and not the old trouble of multiple strictures of the urethra. This condition was due, in my opinion, to the accumulation of the salts of the urine upon a particle of mucus or pus within the bladder; it certainly did not arise from any renal affection as at that time there were no symptoms referable to these organs.

He was very despondent and as he had been told that there were drugs and springs whose effect was to dissolve "gravel," and thus enable him to get well without again having to undergo a surgical operation, he asked my opinion, which was that it would be utter folly to attempt

a cure in that way and I accordingly urged him to come to St. Louis as soon as he could get his affairs in shape. In spite of this advice he went to some mineral springs where he thought he obtained some relief, and it was not until June that he again consulted me. Immediately upon his arrival I sent him to St. John's Hospital and performed the first suprapubic lithotomy on him.

I did not sound him as a preliminary measure because I did not deem it prudent to subject him twice to the danger of the anesthetic, it being my intention to sound him after he had been placed on the table, and if I found a stone to then operate, and if not, possibly to deal with the case by draining the bladder above the pubes. The previous passing of the stone, coupled with the existing symptoms, however, I think justified me in making the diagnosis and telling him that I proposed to cut him. Under ether I passed a searcher and came upon the calculus and then proceeded to the operation which proved extremely easy. Having inflated the rectum with a rubber bag I found not the slightest difficulty in reaching the bladder, and was very much surprised at the space between the lower end of the incision and the upper without coming upon the prevesical fold of peritoneum, which was not in the field at any time during the operation. Two stones, the combined weight of which, without including the loose urinary sediment washed out, was 370 grains, were removed and a drainage-tube left in the bladder until the irritation which it caused led me to remove it four days later. The bladder was washed out daily with hot boric-acid solution, and aside from the discomfort produced by the wetting of the dressings and clothing the patient's condition was so good as to astonish those of his friends who had seen the condition in which he was when he arrived. He was back at work exactly twenty-seven days after the operation. I instructed him to be careful lest the cystitis return, and with that end in view I ordered the daily washing out of the bladder through a soft catheter until further orders. How faithfully my instructions were carried out the subsequent history will show.

Although he passed the sound upon himself regularly once a week he failed entirely to carry out the other instructions after the first few weeks, with the result that in September of this year (1898) I received a letter from him stating that he was in a terrible condition and that it was impossible for him to retain his urine at all, and that it was constantly running from him and necessitated his having to carry a urinal. He also stated that he felt quite sure that he had another stone and wanted again to know if there was no way of getting rid of it without another operation. I, of course, replied that there was no way and advised him to come to me at once. On Monday, October 3rd, I received a telephone message from one of his friends requesting that I call at his home without delay, as my patient had just arrived on the train and he feared was dying. I hastened to make the call and found my former patient, who had now reached his sixtieth year, in a condition closely bordering on dissolution. His weight, which in health had been in the neighborhood of 150 pounds, was now not more than 80, he was haggard and drawn, pulse 128, and he was under the influence of narcotics, which had evidently been given to him for some time to control the frightful paroxysms of pain. His condition was such that I feared I should never be able to get him on the table in order to sound him, much less to perform an operation as grave and attended by as much shock as lithotomy in the event of my finding a stone. However, as it was necessary to do something to try and avert the apparently approaching fatal issue, I at once introduced the searcher and immediately came upon a stone of considerable dimensions, but I did not prolong the examination beyond the time absolutely necessary for making a diagnosis. He was so weak and so completely under the influence of opiates that the examination was practically unnoticed; but as his condition had so alarmed his hosts, who were fearful that he would die on their hands, I had him removed to the hospital, where I proposed to attempt by nourishment and stimulants to get him into such a condition as would justify an attempt at operation to relieve his symptoms.

With that end in view I put him on salol, milk punches, and concentrated nourishment, and ordered the bladder to be washed out daily with hot boric-acid solution. I hoped in a week or so to get him into something like a fair condition to bear the ordeal, although several of my medical friends expressed the opinion that he would never live through it even if I got him on the operating-table. He began to slowly gain in strength, so that on Sunday, October 9th, I concluded to make the effort.

Having given a preliminary hypodermic injection of strychnin a few minutes before he left his bed he was taken to the operating-room and the administration of chloroform begun, but it was borne so badly that ether had to be substituted, and it was with the greatest difficulty that anesthesia was finally induced. The searcher was then introduced and through it about 4 ounces of hot boric-acid solution injected, when it was very easy to feel and hear the stone. The searcher was left *in situ* and its handle entrusted to an assistant, and the rubber bag was then introduced into the rectum and filled with water. The incision was made through the old scar and owing to the density of the cicatricial tissue great difficulty was experienced in recognizing the different structures, in great contrast to the first operation, which was remarkably easy of performance and during which, as observed before, the prevesical-peritoneal fold never came into the field. After considerable delay the bladder was finally reached and incised upon the point of the searcher, two silk ligatures having previously been passed on each side of the proposed incision to be used as retractors, when there was an immediate gush of pus and solution. The searcher having been withdrawn, the finger was introduced into the bladder through the incision, the stone located and then grasped by the forceps and removed. The extraction was rather difficult owing to the small size of the incision and the inelasticity of the tissues, and in consequence the peritoneum was torn and a loop of small intestine forced into the wound. This was immediately replaced and the tear in the peritoneum sutured with a fine continuous-silk suture. After thoroughly irrigating the bladder a rubber drain was secured in place, the

dressings applied, and the patient put to bed surrounded by hot-water bottles.

His condition immediately after the operation was anything but favorable, but reaction finally took place, so that at nine o'clock that evening he was doing well, with a temperature of 99° F. and a pulse of 84. After that the temperature never exceeded the normal, and the pulse varied between 72 and 78. He took nourishment well and was free from pain, the only discomfort from which he complained being the annoyance produced by the constant wetting of the dressings by the urine. The drainage-tube was removed on the third day, but the urine continued to flow through the wound for two weeks longer. The cystitis, of course, improved on the removal of the cause, and under appropriate local treatment. The patient left for his home in Texas on Sunday, October 30th, that is, twenty-seven days from the day of his arrival in St. Louis, and exactly three weeks from the day of the operation, with the wound entirely healed, and firmly convinced that he is hard to kill, an opinion also entertained by all who have seen the case.

The question naturally presents itself in connection with these two operations whether the selection of the suprapubic method was justified in preference to either the crushing and rapid evacuation method of Bigelow or the cutting operation through the perineum. This subject was thoroughly canvassed at the time of the first operation for stone, and it was deemed inadvisable to select lithotrity on account of the previous condition of the urethra, and also on account of the fact that drainage of the bladder through the wound was absolutely indicated. The operation of cutting through the perineum was rejected particularly because of the dense cicatricial tissues which had resulted from the sloughing after the attack of extravasation as well as the consequence of the external urethrotomy. Had the case not been complicated by these conditions there is no doubt that I might have selected one or the other of these procedures, lithotrity, more than likely, as on neither occasion were the stones either of such size or hardness as to render the operation difficult.

As mentioned above, the first operation of lithotomy was ideal in simplicity, and the ease with which the bladder was found and opened, there being ample space between the upper angle of the incision and the symphysis pubis for all necessary manipulations; whereas, on the other hand, the second of these presented grave difficulties, and the accident above referred to, the protrusion of a loop of intestine into the wound, was the direct result of the necessarily small incision, and the drawing down of the prevesical peritoneal fold into the scar of the first operation. That such an accident might have been avoided I doubt very much, and yet should it happen to me again I should certainly regard it with less dismay than the first time, as I shall have less fear of infecting the peritoneal cavity by pus and septic urine, both of which were prevented from flowing into the opening. No attempt was made to wash out the cavity.

Chloroform was used for the external urethrotomy, and was well borne; ether was used for the first lithotomy, and the patient not only took it well, but there was very little nausea after it. In spite of the fact that he had taken both anesthetics well on former occasions, I was fearful, owing to his extreme debility, that we should meet with an accident, and yet selected chloroform on account of the damaged condition of the kidneys (there were decided evidences of pyelitis), but he took this agent so badly and his condition became so alarming, that ether was substituted. In connection with the above it is appropriate to pay tribute to the care and skill which Dr. Willis Hall exercised in handling the anesthetic, and it was undoubtedly largely due to him that the operation could be completed, if, indeed, begun.

MEDICAL PROGRESS.

The Absorption of Salt Solution Through the Rectum.—ELTZ (*Therap. Monatshefte*, September, 1898) advocates the use of salt solutions in rectal injections in order to relieve thirst in cases in which water cannot be administered by the mouth. In a case of eclampsia after absorption, the patient's teeth being spasmodically closed, he found it of advantage to administer large quantities of salt solution in this manner. The fluid was absorbed, producing an abundant perspiration and flow of water through the kidneys. His experience with this method of treatment is limited, but thus far good results have followed its use, and he is inclined to think that it will be found helpful in any acute attack of nephritis associated with edema. From a pint to a pint and a half of the solution may be given at one time, and be entirely absorbed. In cases of severe hemorrhage and repeated vomiting the benefit of this treatment is obvious. It also increases the diaphoretic action of other remedies.

The General Practitioner and Earache.—SPRAGUE (*Atlantic Med. Weekly*, August 20, 1898) asks and answers the question, "What is the General Practitioner to do in cases of Ear-ache?" The pain may indicate (1) otalgia, reflex or local, with no sign of inflammation; or (2) inflammatory conditions of the middle ear; or (3) inflammatory conditions of the external ear. The pain is in itself the most important symptom, and the physician must, therefore, carefully ascertain its character, duration, and location, as well as make a thorough examination of the ear, inside and outside. In otalgia there is no disturbance of hearing and no change in the appearance of the ear or the drum-membrane. The pain is reflex in character, and comes usually from carious or unerupted teeth, ulcers in the throat or nasopharynx, tonsillitis, anemia, neuralgia, hysteria, etc. In inflammatory conditions of the middle ear there is almost always deafness from the beginning of the attack. There is more or less hyperemia and bulging of the drum-membrane, according to the character of the inflammation—catarrhal or purulent—and the amount of fluid present. The application of heat, either dry or in the form of a douche, accompanied by a good sweat and a saline cathartic, will abort most cases at an early stage. The instillation of various drugs into the external ear has sometimes a good

effect, due apparently to the heat of the fluid instilled. If the drum is much distended it should be lanced in its posterior lower quadrant, after the external ear has been thoroughly cleansed and sterilized, and the little operation should be carried out under strict antiseptic principles. If this is done the membrane will heal as soon as the discharge ceases. After the incision has been made the ear may be cleared by the application to the nostril of Politzer's air-bag. But this should not be done unless the nasopharynx has been first cleansed, so that the infectious material shall not be blown up into the ear. If there is much discharge in the nose this part of the operation had best be omitted. After all discharge has ceased and the membrane has healed, it is desirable to use the air-douche for some days to prevent adhesions, which might impair the hearing.

Young children are often unable to localize the pain in ear-ache, and so in all cases of indefinite pain in the head the membrane should be examined in order to detect trouble. If this were regularly done many serious complications would be avoided. Local measures should be tried for only a few hours, and then if they do not give relief and the membrane is bulging, it should be incised without further delay. After incision the ear may be irrigated every few hours, according to the character and amount of the discharge, with hot boracic acid or hot bicarbonate of soda solution, and the physician should keep sharp watch of the mastoid region for any possible extension of the trouble to the cells of this bony process.

Life Prolonged by Artificial Respiration for Three and a Half Hours after the Cervical Cord Had Been Crushed.—SMITH and CLEGG (*Med. Chronicle*, September, 1898) describe their experiences with a cab-driver, who, while drunk, fell from his box, striking on the back of his head. He was at once taken to a hospital, which he reached in a pulseless condition, although the heart was still beating feebly. There was no attempt at respiration. Stimulants were administered, and artificial respiration at once commenced by Sylvester's method. The radial pulse-beat soon became full and strong, but as soon as artificial respiration was stopped there was no attempt at respiration on the part of the patient. The patient became sufficiently conscious, however, to give his name and mutter indistinctly several words. There was complete paralysis of all the muscles below the neck. After two and a half hours the thorax gradually became rigid, making artificial respiration more difficult, and an hour later the patient died. There was a fracture of both the axis and atlas, and the cervical cord was crushed almost into a pulp at the level of the body of the axis. There have been several cases of fracture of the axis reported, some of them resulting fatally, and others terminating in recovery. It was particularly interesting to note in this case that after almost complete division of the cervical cord life was continued for over three hours. As the accident occurred in the neighborhood of a hospital, not over four or five minutes elapsed before artificial respiration was commenced.

Present Methods for the Operative Treatment of Pharyngeal Adenoids.—DELAVAN (*N. Y. Med. Jour.*, October 29, 1898) discusses the different methods for the removal of pharyngeal adenoids. The instruments which have been invented for this purpose may be classified into four groups, as they act upon the principle of (*a*) the curette, (*b*) the forceps, (*c*) the wire-loop, and (*d*) the adenomatome. Of the curettes, the small ring-knives are useful for operations upon the adult with the aid of the mirror and local anesthesia. Gottstein's knife, which is very popular, has the advantage of working rapidly, and the disadvantage of causing a great deal of pain, and of removing only a portion of the growth in many instances. The forceps is a much surer instrument, and can be turned in every direction to seize the masses which it is desired to remove. It causes less bleeding than cutting instruments, and altogether is the most satisfactory, according to Delavan, of any instrument yet devised for this purpose. The adenomatome is a dangerous instrument. It is scarcely possible that its blades will fit accurately the adenomatous surface, and hence there is great danger of cutting too deeply in places. The wire-loop has been given up on all sides. The writer emphasizes the idea that the operation for removal of adenoids is by no means a simple or an easy one. Its performance requires considerable knowledge, experience, and skill, and is best carried out under complete anesthesia with ether. The patient should remain in bed for twenty-four hours after the operation to avoid "catching cold."

THERAPEUTIC NOTES.

The Treatment of Gonorrheal Infection of Joints and Tendons.—NASSE (*Centralbl. für Krank. Harn-und Sexual-Organe*, September, 1898) has had an extensive experience in the treatment of gonorrheal infection of joints and tendon-sheaths. He recommends rest with compression, to be followed by a stiff bandage—either starch or plaster of Paris. Puncture of the capsule, with irrigation, is only to be adopted in chronic cases marked by recurrences. Fixation must not be too long-continued. It should be followed by passive motion and massage. Hot bathing is also helpful, and injections of iodoform may be used. In very bad cases arthrotomy has to be considered. The writer places no reliance upon internal medical treatment.

Partial Blindness Following the Administration of Potassium Bromid and Passion Flower.—HARNSBERGER (*Vir. Med. Semi-monthly*, October 7, 1898) had occasion to prescribe the following mixture to two patients:

℞	Potassium bromid	ʒ j
	Fl. ex. Passion flower . . .	ʒ ivss
	Water	q. s. ad. ʒ iv.

M. Sig. One teaspoonful four times a day, last dose at bedtime.

One was an anemic girl troubled with faintness and tenderness of the right ovary and the other one was a robust laborer whose attack of faintness and cardiac palpitation was brought on by the excessive use of tobacco and indiscretions in diet. The same preparations from which these prescriptions were compounded were used in prescriptions ordered for several other persons without

any unpleasant result following; but the two patients above referred to became dizzy and partially blind some hours after taking the medicine. The blindness disappeared a couple of days after the medicine had been discontinued.

Recovery from a Large Dose of Hydrocyanic Acid. — KOLIPINSKI (*Maryland Med. Jour.*, October 22, 1898) reports a case of recovery from hydrocyanic-acid poisoning. A man, aged forty-two, neurotic, and melancholic, took prussic acid with suicidal intent. Twenty minutes later he was found lying on his bed presenting the following symptoms:

Face flushed; eyelids half open; eyeballs slowly rolling; pupils dilated; pulse accelerated; deep coma; deep, rapid, peculiar breathing, with sobbing inspiration. The breathing was like that in the coma of diabetes or grave cerebral appoplexy, and can be noticed experimentally in a dog after a lethal dose of potassium cyanid.

There had been involuntary urination and defecation. The tongue was swollen and purplish. The breath had a heavy metallic odor, like potassium cyanid.

The patient was given a subcutaneous injection of $\frac{1}{40}$ of a grain of sulphate of atrophin, 10 grains of citrate of caffein by enema, and 4 or 5 enemata containing each a teaspoonful of aqua ammonia in half a cup of water. Later, when the patient was somewhat aroused he was given aromatic spirits of ammonia by the mouth. Consciousness returned in two hours. During his revival the pupils were contracted, there was very rapid breathing, with dyspnea upon the slightest effort, as whenever he tried to talk or swallow. He had ten or twelve evacuations in the next few hours, but in twelve hours from the time the poison was taken his condition was the same as before it had been swallowed. There were no after-effects, except, for a few days, dysenteric stools without blood, the result of ammonia injections.

The quantity of poison swallowed was one-half ounce of the official acidum hydrocyanicum dilutum, U. S. P., containing two per cent., or 4.8 grains of anhydrous acid.

Treatment of Neuralgia and Headache with an Ether Spray.—HAMM (*Therap. Monatshefte*, October, 1898) has revived an old method of treatment, the ether spray, and applied it to the relief of headaches and neuralgia with good results. The apparatus is one which can be had at any drug-store, and the expense is slight. He has treated a large number of patients in this manner and has found the method to fail in only a single instance. Usually one application is sufficient to effect a cure. The ether is sprayed upon the most painful part until there shows a thin white layer of frost. The pain is relieved at once and usually does not recur. In mild cases it is not necessary to freeze the skin.

Bicarbonate of Soda as a Dressing for Suppurating Wounds.—AUGE and CASTERET (*La Presse Med.*, September 24, 1898) say that bicarbonate of soda used in a two-per-cent. solution is an excellent treatment for suppurating wounds. They have used it in some sixty cases with great satisfaction. The solution is not bactericidal but it acts in a wound as an antiseptic, probably because its alkalinity preserves the tissues and puts them and the blood in the best condition to overcome the germs. Moreover, the healing of a wound according to Preobrajenski is not exclusively due to the destruction of germs. It depends upon the capillary circulation in the wound. If the liquids in the wounded area pass from within the body outward they carry off toxins; if they pass from without inward general infection follows. This view has been proven by a number of experiments. Bicarbonate of soda by dissolving the fatty matter of the skin stimulates the secretions through all of its pores while keeping all the tissues in a vital condition. It is in a certain sense, therefore, a physiologic dressing.

A Malted Food for Nursing Infants suffering from gastro-intestinal disturbances with symptoms of acid intoxication is recommended by KELLER of Breslau. Its usefulness is due to the fact that it is rich in alkalin substances and that it substitutes hydrocarbons for an excess of casein and fats. It is prepared as follows:

A. Mix 1½ oz. of wheat flour in ⅓ quart of milk and strain.

B. Put 3 oz. of malt extract in ⅔-quart of water at 122 F., and add 2½ dr. of a 11-per-cent. solution of potassium carbonate.

Mix A. with B. and boil. Use in full strength or diluted with water according to the age of the infant, whose general condition is said to improve rapidly under this treatment.

Facial Paralysis Cured by Salicylate of Soda.—CATRIN (*La Presse Med.*, October 8, 1898) mentions a case of paralysis of the seventh cerebral nerve. The patient presented the following symptoms: Paralysis of the muscles of the face, diminution of the salivary secretion, disturbances of hearing and taste, and deviation of the eye downward when attempts were made to close it. Thinking that the trouble was of a rheumatic origin Catrin put his patient upon salicylate of soda, 30 grains per day, and this dose was gradually increased until 60 grains per day were taken. This was continued for two weeks and then was gradually diminished. Altogether the patient took the drug three weeks. On the sixth day of treatment sensation begun to return. In two weeks the patient could completely close his eyes and all disturbances of sensation were at an end. In three weeks there was no longer any trace of the trouble.

For Blepharitis Marginalis.—Formaldehyd, at first in one per cent., later in two-per-cent. solution, is recommended for daily application in the following manner: The eyelid is raised and its margin rubbed gently with a small cotton tampon wet with the solution, care being taken that none enters the eye. This process is continued with clean tampons until all the crusts are removed. Finally, a little pure oil is applied. A cure is generally effected, even in severe cases, within one month.—*Moulton.*

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed *exclusively* to THE MEDICAL NEWS will after publication be liberally paid for (accounts being rendered quarterly), or 250 reprints will be furnished in place of other remuneration. When necessary to elucidate the text, illustrations will be engraved from drawings or photographs furnished by the author. Manuscripts should be typewritten.

STREET CLEANING AND HEALTH.

NEW YORK has had her first experience of the winter under the new régime in the removal, or rather non-removal, of snow from the streets; it has been far from satisfactory to the citizens or commendable to the régime. So large a snow fall was unexpectedly early in the season but that fact hardly justifies the utter lack of anything like systematic effort for the immediate removal of the accumulation. Others have said how important to New York in a commercial sense and how much absolute loss of money to business men there is in the continuance of snow-blocked streets. The first consideration, however, must be the health and lives of the people. To the thousands of citizens who daily tread the streets of New York the persistence for days and weeks of slushy street crossings and monumental piles of mingled filth and snow is a constant menace to life and health. The doctors of the city in their private and dispensary practice have seen the effect of this state of affairs in an increase of respiratory troubles of all kinds. Any amount of money that will secure the prompt removal of snow and the avoidance of slush and mud will be well and profitably spent for the health of the citizens. One thing remains to be insisted upon and that is the supreme right of the pedestrian, which is likely to be lost sight of in the care for business facilities and the insistent interests of large corporations; therefore, street crossings should be the first thing to engage the attention of the Street Cleaning Department and a determined effort made to keep them in passable condition. This would undoubtedly secure the greatest good for the greatest number.

ANOTHER CHRISTIAN-SCIENCE MANSLAUGHTER.

THE death from diphtheria of a sixteen-year-old girl who had had only Christian-Science treatment, or rather lack of treatment, is announced this week at New Britain, Conn. An English coroner's jury under similar circumstances has brought in a verdict of manslaughter. The crime is just as great on this side of the water, and no false motives of consideration for the foolish parents should prevent the bringing of the guilty parties not only to justice, but before the bar of public opinion. No stigma is too black to attach to those who allow superstition, *i.e.*, the imposition of their own foolish faith, to carry them into an invasion of the sacred rights of human life. Diphtheria, especially, has become in these later years one of the most tractable of human ailments and for it, more almost than for any other disease, can the physician "work wonders" by the methods that modern scientific medicine has put into his hands. The crime in the case is made all the more black by this consideration. Let us hope that a well-deserved punishment will be meted out in this instance, as a warning to the thousands of others who have allowed themselves to be senselessly carried away by the foolish nonsense of what has been well called Unchristian Nescience.

PATENT-MEDICINE TESTIMONIALS FOR SALE.

THE following from *Printer's Ink* seems to need no comment. It is dated at Chicago, and addressed to the manufacturers of a certain remedy who are well known for successful advertising:

GENTLEMEN: I have seen your add in Chicago daily papers, and would be glad to know if you could use one or two prominent citizen's testimonials and photos as to merits of your remedy.

Say a senator, judge, representative, or county official whose face and testimonials are valuable. I furnished three photos and testimonials to a big patent-medicine company, and think I can handle three or four more. If you can use any of them, and are willing to *pay for them* (italics ours), I would be glad to furnish same. An early reply will oblige. Yours very truly.

We miss the prominent clergyman and the college professor from the above list of honor. Are their photos and testimonials too valuable to be quoted thus in the open market, requiring special and personal negotiations to secure them, or have they become more or less literally such a drug on the market that they are now hawked about in batches, and are no longer considered worthy of anything but passing attention from the gilt-edged advertising agent?

PROFESSOR KOCH AND QUININ IN MALARIA.

The following anecdote in connection with Professor Koch is told by an Italian medical journal. He was in Rome for the purpose of studying malaria, and going through the wards of the Santo Spirito Hospital one morning he noticed a patient seemingly in the last stages of collapse from pernicious malaria. He remarked that he would like to be present at the autopsy next morning and hoped to secure from the spleen some interesting specimens of the estivo-autumnal type of the malarial parasite. Judge of his surprise next morning to have the patient greet him from a distance as he entered the wards. He demanded how the miracle had been done and was told that they attributed it in the hospital to intravenous injections of quinin after Professor Bacelli's method. It is not told what Professor Koch then said. Considering the circumstances his remarks would at least be interesting to the medical world. The story seems almost too timely and apt to be entirely true, but as the Italians themselves say: "Se non é vero é ben trovato," if not true it is a most happy invention. It also indicates how firmly the Italians believe in the use of quinin in all forms of malaria, despite the recent protests against its use by people who have but little practical experience with it.

THE TOXIN THERAPY AND MALIGNANT DISEASE.

Two recent communications show that this interesting chapter in surgical therapeutics, the effect of toxins upon sarcomatous growths, is not yet closed. Mr. Battle presented before the Medical Society of London (*Lancet*, November 19, 1898) a man who had been treated with Coley's fluid for inoperable sarcomatous growths of the shoulder. Microscopic examination of excised sections showed that the growth was composed of spindle-cells and large cells. After three-months' treatment no trace of the tumor was left. Mr. Mansell Moullin, commenting on the case, congratulated Mr. Battle on having shown the first authentic case in England of dispersion of tumor by Coley's fluid. He himself had had three cases, but under such circumstances that the diagnosis could not be confirmed by the microscope. In the case under discussion, however, he had seen the tumor and the secondary growths. He had also examined the microscopic sections, and he could not conceive that the tumor was anything but a sarcoma.

Dr. Maurice H. Richardson, surgeon to the Massachusetts General Hospital, reports in the December number of the *Annals of Surgery* the details of a striking experience with ordinary severe wound infection, causing the disappearance of a tumor which microscopic investigation had shown to be infiltrating round-cell sarcoma. The tumor had infiltrated the tissues so widely in the scapular and axillary regions that operation begun for its removal had to be discontinued. Extensive and severe infection of the operation wounds followed, and to the surprise of all who had seen the tumor and knew the microscopic diagnosis, the tumor disappeared during the suppurative process, and did not return.

The attitude of the surgeon toward so-called cures by any but surgical means of malignant disease is very naturally one of incredulity, but even a proper conservatism has its limits, and to put aside cases like these without further effort is to impugn wantonly the clinical judgment of thoroughly conservative surgeons and assume error of diagnosis on the part of capable pathologists. The outcome of further observations along this line must in any case be of benefit to scientific medicine, for if they do not finally furnish us with an effective therapeutic aid, they will, at least, have proved of service to higher medical criticism by supplying us with crucial tests of surgical and microscopic diagnosis.

AMERICAN SURGERY AND THE GASSERIAN GANGLION.

THE surgery of the Gasserian ganglion is peculiarly American. We say it with not a little pride, for it promises to have a definite place in the surgical treatment of that awful malady, facial neuralgia, in its most obstinate forms. The demonstration of the feasibility of the removal of the entire ganglion and the elaboration of the operative technic we owe entirely to American surgeons. A distinctly new advance in the relief of the most racking pain that human nature can be called upon to endure is the result of their efforts.

Slowly the realization of this fact percolates through the hardened strata of solid glacial conservatism that separates us from our Continental European brethren. Our English cousins have not been so slow to recognize the value of the procedure and one of them, at least, has been in at the making of a new chapter in surgery. In Germany, with notable exception of Krause of Altona and Kocher of Berne, the surgeons have paid very little attention to it. France has taken to it more kindly, but a perusal of the proceedings of the last French Surgical Congress, with the discussion of the treatment of facial neuralgia and incidentally of the resection of the Gasserian ganglion, will convey the same impression as would a corresponding discussion in our own country some five years ago. At that time all was tentative; nothing was definitely settled as to operative technic, post-operative complications, final results, or even the question of the justifiableness of the operation.

We note the fact to congratulate American surgeons on it. We are not far from a new century in which we feel sure that distinctly American advances in medicine and surgery will not be so rare as to be deemed worthy of special congratulation.

VASCULAR HYPOPLASIA, OR LYMPHATIC DIATHESIS?

A YOUNG man twenty-three years of age, during a reasonably quiet boxing-contest in England, died after a blow, not over the heart but some distance from it, and not delivered with special energy. The only suggestive post-mortem finding in the case was an extremely small heart. This brings up the interesting question as to what is to be considered the cause of death in such cases.

Years ago Professor Virchow described certain cases of fatal chlorosis in which the whole vascular system was hypoplastic, and as the development of this is due to the reduced pressure exerted upon it by the amount of blood in the organism, it seemed clear that the blood-making organs were primarily deficient, thus accounting for the persistent chlorosis. It was noted that these subjects with persistent chlorosis were peculiarly irresistive to intercurrent disease, that the acute infections carried them off easily, that they did not stand trauma well, that they were especially liable to succumb to the shock of surgical operations, and formed a notable proportion of those who died from an anesthetic. Later, the elder Professor Paltauf, from his immense material in the Medico-Legal Department of the General Hospital at Vienna, selected a series of cases resembling these, but not always presenting post-mortem this hypoplastic condition. They were young persons, usually under twenty-five years of age, upon whom autopsies were performed because of sudden death. This had occurred either in the course of an acute infectious disease, such as pneumonia, typhoid fever, or influenza, or more suddenly from some slight shock, as diving into cold water, a slight blow, especially under excitement, a slight accident if accompanied by fright, and, finally, insignificant surgical procedures and anesthesia. In a large number of these subjects, some with and some without the vascular hypoplasia described by Virchow, he found hypertrophy of all lymphatic structures: usually, an external lymphatic polyadenomatous condition, nearly always, enlarged tonsils and hypertrophy of follicles at the base of the tongue, and invariably enlargement and multiplication hyperplasia of the follicles of the intestine and enlarged mesenteric glands. He called this condition the lymphatic diathesis, and the Vienna school attribute most of the otherwise inexplicable sudden deaths to it. We understand that a distinguished pathologist in Vienna even attributes the death of Langerhaus' child in Berlin to this lymphatic constitution. Our readers will doubtless remember this as the case in which the child of an assistant of Professor Virchow died immediately after the injection of diphtheria serum, given as an

immunizer, the child not having diphtheria, but only having been exposed to contagion. While they are not in the least of the opinion in Berlin that the antitoxin was the cause of the death, they smile very knowingly at the diagnosis *in distans* of the Vienna school.

Meantime, the medical world is divided as to whether the Berlin or Vienna explanation of these sudden deaths is to be accepted. They are not so different from one another but that one might accept both, for they are mutually exclusive. It is evident, however, how important for the final solution of this question is the careful observation of each little detail of clinical history, and, if possible, the post-mortem findings of these patients who die young and without what would seem adequate cause. Even during life the evidence of the existence of the lymphatic diathesis or of hypoplasia of the vascular system, is not so obscure but that the careful physician should be able to detect them, and by the institution of proper prophylactic measures and the avoidance of the slight shocks so fatal in these cases materially lengthen patients' lives. For anesthetists it is of the utmost importance that they should learn to recognize the symptoms of these conditions. The careful investigation of the condition of all patients about to be anesthetized with special reference to the existence of these conditions would, undoubtedly, do more to improve the anesthesia mortality statistics than any of the many vaunted methods of safe anesthesia or any mixture of special anesthetics.

THE "LANCET" AND THE COLOR OF NEWLY BORN NEGRO CHILDREN.

THE London *Lancet* is in a quandary. A French physician, Dr. Farabery, made the assertion some time ago after some slight experience with Africans on exhibition in Paris that negro babies up to the age of seven days are similar in every respect to white babies. This was published in *Pædiatrics* in this country and was denied. Those who denied the statement, however, did not themselves agree as to what the color of a newly born negro boy is. An Alabama medical man says negro babies are black from the very beginning, a Missourian says they are sallow or creamy-white, hence, the *Lancet's* dilemma. The American doctors, from their greater experience ought to know more about the matter than Dr. Farabery, but then they do not agree. The editor suggests that practitioners in the English colonies in South Africa be asked to decide the question, but there need surely be no necessity for going so far. Since our English contemporary takes it so seriously will not some one with a newly-born piccaninny or two on hand tell us the exact color of the precious treasures and so settle an important medico-anthropologic question?

ECHOES AND NEWS.

Death from Football Injuries.—A member of the football eleven of Ohio University died recently from injuries received two weeks previously while playing the game.

Rush Medical College.—Dr. Sanger Brown has resigned his position as Professor of Mental and Nervous Diseases in the faculty of Rush Medical College, Chicago.

The Presidency of the New York Academy of Medicine.—The nominees for president of the Academy of Medicine to be voted for at the next meeting are Drs. Wm. H. Thomson and Egbert H. Grandin.

Bubonic Plague in Madagascar.—The Minister of the Colonies announces that a plague has broken out in Madagascar, and that the situation presents an exceedingly grave aspect. The disease is distinctly of the bubonic type.

The O'Dwyer Scholarship.—The trustees of Columbia University have established in the College of Physicians and Surgeons a scholarship to be known as the O'Dwyer Scholarship, in recognition of Dr. Joseph O'Dwyer's professional labors.

A Medical College Burned.—The Medical College of Indiana, a four-story brick building in Indianapolis, has been almost completely destroyed. The loss is estimated at $30,000. Dr. Shobe, who slept in the building, was so badly burned that he cannot live.

The Prognosis in Alopecia.—A dermatologist began a paper on alopecia as follows: "Faith is usually pictured as a maiden clinging convulsively to the rock of ages. I think a more impressive representation would be that of a bald-headed patient rubbing vigorously into his scalp the remedy prescribed by the bald-headed specialist in skin diseases."

Bodies of the Santiago Dead.—The War Department has decided to adopt, at once, the suggestion of General Wood, in command at Santiago, that the removal of the bodies of American soldiers from that section of Cuba be deferred until February at the earliest. This is a sanitary precaution which, it is felt, must outweigh other considerations.

Dr. Huidekoper Appointed Chief Sanitary Officer at Havana.—It is reliably reported from Washington that Dr.

Rush Huidekoper has been selected by President McKinley to fill the position of chief sanitary officer at Havana. It will be his duty to put into effect the suggestions of the late Colonel Waring. The President has authorized the expenditure of $50,000 for this purpose.

Ft. Monroe's Military Hospital.—Ft. Monroe will soon be one of the most important military hospital stations in the country. The hospital is named the Josiah Simpson Hospital, and has during the past four months accommodated 1500 sick and wounded soldiers, of whom about 500 still remain. It is now proposed to increase the capacity of the hospital to 2500 beds by the erection of five additional buildings.

Bequests of Edward Austin.—The late Edward Austin of Boston left nearly $1,000,000 for educational purposes. Of this Harvard is to have $500,000, the Massachusetts Institute of Technology $400,000, and Radcliffe College $30,000. The income of these large bequests is to be used for scholarships, not professorships. The sum of $10,000 is given to the Bacteriological Laboratory of the Harvard Medical School.

Which Was First, Mind or Medicine?—This question is taken from "Science and Health," the book written by Mrs. Eddy, the "Mother" of the Christian Science Church. There is really no one who can truthfully answer this question. Perhaps Mrs. Eddy knows the answer, but she doesn't give it in her book. At all events, it *is* quite immaterial which was first. Upon such quibbles as this does the Christian Scientist rest her faith.

Health Conditions at Manila.—The following report by General Otis shows a decided improvement in the health of the troops in the Philippines: "November deaths 26 as against 45 for October. Sick-rate in command about the same as among troops of other governments serving in tropical countries. One third of present sick suffering from typhoid and malarial fevers, one-sixth from intestinal troubles, and the remaining half from ailments slight in character."

Colonel Roosevelt on Medical Affairs at Santiago.—Colonel Roosevelt testified before the War Inquiry Commission that the medical supplies at Siboney were "entirely insufficient;" there were not enough doctors, and the condition of the wounded was "appalling during and immediately after the fighting." The privations as regards medical supplies and food were greater than it was necessary to have them, "the system which procured inexperienced officers" being responsible.

Health in the Philippines.—Professor Dean C. Worcester, in his book on "The Philippines," states that the climate in these islands is especially severe on women and children, and doubts if many successive generations of European or American children could be reared there. Malaria and diseases of digestion, smallpox and cholera (the last uncontrollable when it once begins) are to be found; leprosy and beri-beri occur, but are not common. The bubonic plague has not as yet gained a foothold.

Meeting of the American Physiological Society.—The American Physiological Society will hold its Eleventh Annual Meeting in New York on Wednesday, Thursday, and Friday, December 28, 29, and 30, 1898. The first day's session will be held at the College of Physicians and Surgeons; the second day's session at Schermerhorn Hall, Columbia University, this session partly in conjunction with the American Psychological Association; the third day's session at the University and Bellevue Hospital Medical College.

Resolutions upon the Death of Dr. Page.—At a regular meeting of the Northwestern Medical and Surgical Society of New York, held November 16, 1898, resolutions were adopted expressive of the esteem and high estimation in which Dr. Richard Channing Moore Page was held by the members of the Society, and of their appreciation of his great medical and literary ability, combined with an indescribable charm of manner which had endeared him to them all. It was resolved that in his death the Society had suffered an irreparable loss.

Breakfast in Cuba.—According to the *American Kitchen Magazine*, at the breakfast of the well-to-do families there stands at every plate a bottle of red Bordeaux or Catalonian wine, which is drunk as freely as water. The food is usually abundant and nourishing. After breakfast and not with it, coffee is served. At breakfast they have the inevitable honey and fruit and eggs, the last being cooked in styles about the same as in the States. In addition, a favorite dish is a small tenderloin steak served with sliced fried potatoes.

The Manhattan Eye and Ear Hospital.—At this hospital during the last year 19,435 patients who made 88,485 visits were treated at the clinics. In the eye department 12,995 were treated, in the ear department 3366, in the throat department 3073, and in the wards 1425, who received 17,863 days' board, of which 6836 were free; 2632 children were treated at the clinics. Treatment was refused to 1579 patients as they acknowledged their ability to pay for medical advice. More than 27,000 prescriptions were dispensed during the year.

Physicians for School Teachers.—The Board of Education of New York City has appointed for the whole city of New York, nineteen physicians (among whom is one woman), whose duties it will be to examine teachers, who are required to present certificates of sound health before they are allowed to teach. Heretofore the teachers had to pay the physician's fee for examination; hereafter, however, the applicant may consult any one of the appointed physicians free of charge and the Board of Education will pay $3 for each examination.

The New York Lying-in Hospital.—The one hundredth annual report of the Society of the Lying-in Hospital has just been issued. It is stated that out of the 51,117 births reported by the Board of Health for the year ending October 1, 1898, in the borough of Manhattan, 23,892 unfortunate mothers were dependent on the care of ignorant midwives, and only 27,225 treated by physicians

in practice. These include all charity patients, and out of that number more than nine per cent., were cared for and nursed by the Society of the Lying-in Hospital.

Life Insurance a Century Ago.—"Sir Mark Sykes offered to pay any one who would give him a hundred guineas down, a guinea a day as long as Napoleon I. lived. The offer was taken by a clergyman present, and for three years Sir Mark paid him 365 guineas per annum. He then thought he had thrown away enough money, and disputed further payment. The recipient, who was not at all disposed to lose his comfortable annuity, brought an action, which, after lengthy litigation, was decided in favor of the baronet."—John Ashton, "History of Gambling in England."

Historical Papers Given to the University of Pennsylvania.—Dr. S. Weir Mitchell, the novelist and historian, has presented to the library of the University of Pennsylvania the original provincial letters of authority to Provost William Smith to collect funds for the College and Academy of Philadelphia, now the University of Pennsyivania, and to John Jay, to collect funds for the College of the Province of New York, now Columbia University. The authority to John Jay is dated March 13, 1762, and bears the signatures of the Archbishops of Canterbury and York, and the Lord Bishop of Winchester.

The Abraham Jacobi Hospital Ward for Children.—A gift of $50,000 for the endowment of a children's ward in Roosevelt Hospital, to be known as "The Abraham Jacobi Ward for Children," is announced. The beds of this ward will be free to all sick children except those suffering from contagious diseases. The object of this gift is to provide clinical instruction for medical students. It is very appropriate that this honor and opportunity for more thorough clinical instruction in diseases of children should be conferred upon Dr. Jacobi, who, by his teaching and his insistent advocacy of the importance of special clinical instruction in pediatrics, has gained deserved recognition for his specialty.

Atropin for Morphin.—The unpardonable mistake of using atropin instead of morphin in filling a prescription for the latter has recently occurred in a New York drug-store. Fortunately, only one dose was taken by the patient, and although the symptoms were most alarming, a fatal issue was avoided. The clerk who compounded the prescription was promptly discharged. The exhaustion due to the unlimited hours during which drug-clerks have been compelled to work has formerly afforded some mitigation of the censure provoked by such mistakes. The reasonable hours of duty prescribed by the concerted action of the New-York druggists, however, no longer permits of this condonement.

Was this a Death from Hydrophobia?—August Bombiadi, aged five, died last week at the home of his parents, Astoria, L. I. He is said to have been bitten by a dog several months before. His injuries were not attended to and though he is said to have suffered comparatively little, spasms were frequent toward the end.—[All deaths after the bite of animals are of marked medical interest owing to the dubious position that many members of the profession in America take with regard to the existence of hydrophobia in this country. Any details of suspicious deaths under such circumstances will be gladly welcomed by us and will be of great service to American medicine in helping to throw light on an important subject.—EDITOR.]

Seeming and "Real"ity.—The *Revista Medica* is a Portuguese medical journal published at Sao Paulo in Brazil. A first glance at the price demanded for subscription might lead one to think that at least there was one place in this cold, cold world where the medical editors' efforts were appreciated at something like their true worth. Subscription for a year costs 10$000 rs; a single number is worth 1$500 rs. But alack and alas it is only seeming and the subscription price, 10 reals, is about the ordinary amount charged for a monthly journal in this country. What a paradise for the advertising manager would be Brazil if the price announced for a page of matter 40$000.rs. had any actual comparison to its seeming in our unfamiliar foreign eyes.

An Infirmary for Students at Harvard.—For some time the building of an infirmary at Harvard University for sick students has been under consideration. The immediate accomplishment of this very laudable purpose is now made possible by a gift of $50,000 from Mr. James Stilleman of New York. The infirmary is to be named after the donor, who also agrees to contribute $2500 a year for four years toward its support. This is, we believe, the first infirmary for sick students to be erected at any of the large universities. It fills a long-felt want, for the possibility of being sick in lodgings has been the nightmare of many a delicate student and no little source of anxiety to his friends. Harvard is to be congratulated on being a pioneer in this as in so many other things that tend to make student life more livable.

One Hundred Average English Boys.—An eminent English physician has made physical examinations of a number of English schoolboys, the sons of well-to-do parents; their ages were between thirteen and fifteen. They were supposed to be typically healthy lads. "Minor imperfections," such as stammering, a tendency to chilblains, defective teeth, and many other failings were not considered. Among the first one hundred 39 were below the average in height and 53 below the average in weight, 68 were below the average in chest measurement, 63 were the subjects of "deformities," such as lateral curvature, pigeon-breast, knock-knee, and flat-foot, 20 had defective sight, 9 had defective hearing, 1 an "abnormal growth," 1 was color-blind, 2 had "heart disease," 2 had hernias, and in the urine of 22 albumin was found.

Malaria, an Announcement.—Many of the troops that suffered severely from malaria in the South and in Cuba have been mustered out. A widespread interest throughout the country on the subject of malaria, and especially its latest differentiated form, the estivo-autumnal fever, has been aroused by the epidemic. A very practical as-

pect of the question is that some of these men will come under treatment for relapses and complications on the part of their home physicians. We are glad to announce then, that we will publish next week Dr. W. H. Thomson's article on the treatment of Cuban malarial-fever, and Dr. Watkins' microscopic specimens of the estivo-autumnal parasite. There will be besides, an editorial review of the subject of nephritis after malaria, and a special article on quinin in the treatment of malaria, especially of the estivo-autumnal type.

Christian-Science Graduates, Announcement Extraordinary.—In the light of recent events we think that the following announcement, which was officially given to the press, may be awarded the palm for consummate self-sufficiency: "Mrs. Mary Baker Eddy, discoverer and founder of the Christian Science, has just completed the examination (*sic*) of a class of about seventy! of the active workers in Christian-Science mind healing, to confer upon them the degrees of the Massachusetts Metaphysical College, as healers and teachers of this system of medicine (shades of Hippocrates!), whose only crowned head is divine sovereignty, whose only priest is spiritualized man" (mainly of the feminine gender). There was a time when we looked to Massachusetts as a model State government in which the regulation of abuses was the care of the enlightened citizens, but that time is no more, it seems. *Quantum mutatus ab illo!*

Enterprising Medical Journalism.—Another new journal has come to us from out of the West. It is enterprising, of course; every journal is which emanates from that resourceful region. A superior advantage claimed for it over its contemporaries is one by which the contributor, for the purpose of elucidating his text, may have his article embellished by his photograph. Only a person absolutely without the esthetic temperament would not be lost in admiration of one of these photographs. The subject scorns the photographer's stereotyped request, "Now smile, please;" instead, through his pellucid orbs, his soul seeks inspiration in the empyrean. It is evident that on the instant of the camera's click the gentleman had in mind Goethe's appeal for "light, more light." It is pleasing to record that this gentleman was not disappointed; light did come to him—in the form of a paper on the use of "Unguentum Hydrargyrum in Syphilis," which accompanies the photograph.

Professor Nothnagel Again.—Professor Nothnagel, the distinguished director of the First Medical Clinic at the General Hospital at Vienna has been once more the subject of uncalled-for newspaper comment. A good deal of unenviable notoriety was forced upon him some time ago by the connection of his name with the outbreak of plague in Vienna, for which he was, as we have explained in these columns, in no sense responsible. This time it is the medical press that is at fault and he has had the pleasure, for such must be the feeling produced, of reading his own obituary in several of the French medical journals. Needless to say it was extremely complimentary; it could scarcely be anything else, for it is generally acknowledged that Professor Nothnagel deservedly occupies one of the highest positions in European clinical medicine. We are happy to be able to state, however, that he is not only not dead but he is hale and hearty for his sixty-six years, enjoying excellent health, and gives promise of continuing his valuable contributions to contemporary medical science for many years to come.

"Hysterical Affections of the Eye" Before the New York Academy of Medicine.—The Section on Ophthalmology and Otology furnished the scientific program at the regular meeting of the New York Academy on December 1, 1898. By special invitation of the chairman of this section, Dr. B. Sachs of the Neurological Section was asked to furnish the paper of the evening upon "Hysterical Affections of the Eye." In an exhaustive article, presenting a review of the bibliography of the subject since 1873, the author devoted himself to the hysterical palsies of the external ocular muscles in contradistinction to the loss of balance among them that gives rise to the several phorias and squints, so interesting to oculists, and to hysterical amblyopia. Except in so far as the loss of power over the recti disturbs binocular vision, hysterical paralysis in them was not shown to differ essentially from the same form of paralysis in other motor regions. Clinical proofs of the existence of these paretic conditions are not wanting, although the diagnosis must often be reached by a process of exclusion. It is well, however, to remember that mental suggestion occupies an important place in their production and presents the key to their successful treatment. Passing to the second part of his subject the writer emphasized the difficulties encountered in the study of affections of the special senses since the observer now finds himself more or less exclusively within the realm of subjective phenomena. The almost endless variations in form and degree of hysterical amblyopia and its not infrequent association with such symptoms as photophobia, ocular tenderness, and even disturbances of circulation, as witnessed by the ophthalmoscope, have led trained clinicians far astray. So frequently has some limitation of the field of vision coexisted with hysteria that its presence has come to be regarded as almost pathognomonic of the latter. As a rule it is symmetrically and peripherally disposed in the two eyes and corresponds in degree, the fields of color perception contracting according to what might be termed the usual formula. The writer had never observed an example of complete central scotoma of hysterical origin. Throughout this entire consideration of the topic the author kept well before his audience his unwillingness to believe in the localization of the malady as manifested by the functional incapacity and expressed his conviction that the cerebral centers at least, if not the higher cortical areas, were mainly at fault.

Dr. H. D. Noyes, in discussion, reported three cases of extreme interest and pointed out in them the important factor played by suggestion in both a causative as well as a curative relation. In answer to a question raised in the paper he asserted that he had seen more than one patient with central hysterical scotoma. Besides the difference in ophthalmo-

copic appearances the tenderness in retrobulbar neuritis is best elicited by pressing the globe as a whole back upon the inflamed nerve, while the ocular tenderness of hysteria is manifested by lightly palpating the globe itself. Dr. C. L. Dana had attended the meeting with the impression that he would find it necessary to defend the large degree of skepticism with which he regarded the highly intangible subject of hysterical paralysis, but he was happy to find the paper so conservative in the views expressed that little was left him for attack. He reminded his hearers of our all but complete lack of knowledge as to the essential nature of hysteria and of the phenomena arising therefrom. He had come to consider hysteria as a psychologic disturbance, if not a true psychosis. In the charts exhibited by Dr. Noyes recording the limitations in the visual fields, he observed that they were shown to be exactly symmetrical in the two eyes. Quite the opposite had been the result of carefully conducted observations made by himself. Dr. Herman Knapp spoke of our want of positive acquaintance with hysteria and asked how it was possible to interpret its resulting symptoms while laboring under such ignorance. The elusive nature of the whole question under consideration reminded him of a Homeric figure by which the unsubstantial was likened to the shadow of smoke. In practice it was quite common, especially among the young, to find ocular affections which are catalogued under the term hysterical, and after convincing himself of the non-existence of a local lesion it was his habit to treat these patients very cavalierly. The fears of the parents and friends were first allayed, after which the condition was in a great degree disregarded.

CORRESPONDENCE.

THE DIFFICULTIES OF ORGANIZING A VOLUNTEER ARMY.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—To the exposure of abuses in recent army management there can be no valid objection. But criticism is a thousand fold easier than performance; and it is far-fetched to expect no mistakes in either appointments or administration in the sudden raising of a raw army. It readily occurs to any one who has had several years experience with volunteer forces that this cannot be done without considerable losses from sickness.

The best man on earth and the smartest angels in Heaven as Secretary of War and heads of army departments could not do it for various reasons, among which are: (1) In spite of medical examinations, a certain percentage of raw men will always be found to lack the physical and moral stamina to endure any hardship. (2) A radical change from home to camp-life will always cause a good deal of sickness. (3) A change from a temperate to a semitropical or tropical climate, especially in summer, is always unhealthy. (4) The proverbial recklessness of youth, in regard to diet and all other habits, always worse under the excitement of the gathering with a multitude, and of the commencement of a war. (5) Nine men out of ten, among newly enlisted volunteers, will pay very little attention, for the first few months, to any orders in regard to camp hygiene. They consider such orders as simply so much "style," "red tape," or "poppycock," and simply ignore them. If a few individuals only did this they could be disciplined, but not readily when nearly all do so. Closely connected with this, and largely the cause of it, is: (6) The considerable proportion of field and line officers elected by popular vote of the volunteers or appointed by State authority who are ignorant, idle, or reckless, or all together, and totally unfit to care for men. Nothing is more common than to see some companies in a regiment, or some regiments in a division, with twice or three times the sickness of other companies or regiments with exactly the same surroundings. Most of these incompetent men can be weeded out in a few months, but not at once. The men will learn to conform to camp hygiene, but not until their own bitter experience has taught them its necessity, and they have learned the value of strict obedience to all orders. (7) The Santiago campaign, involving exposure in midsummer to a tropical climate under the worst circumstances, must have caused a heavy percentage of sickness with the best possible management.

Making reasonable allowance for these, under the circumstances, largely unavoidable causes of sickness, it is not reasonable to ascribe a large amount of sickness to the neglect or incompetency of any one government officer, or of several of them. The actual statistics of sickness are less than of any other large army ever raised in so short a time. They are very much less than in 1861–5. It may be said that this should be so because hygienic knowledge has much increased since that time. This is true so far as the most enlightened of the people, and a large proportion of the medical profession is concerned; it is not true, to any great extent, of the bulk of our population.

It may also be said that our troops should have less sickness because in their own country in time of peace. This is not so true as it at first appears. The unlimited opportunity to buy all sort of huckster's supplies, many of these bad or stale, and the injudicious sending of dainties from home, had considerable to do with the sickness. The keeping the men in any one camp for months at a time, whoever was responsible for it, was a grave error.

Nothing is gained by any attempt at shielding any mistakes or wrongdoing on the one hand, or by railing accusations on the other. If a large army is again suddenly raised after thirty-three years of peace, there will be a great deal of sickness in it. The only way to even partially avoid this would be for the militia every year or every few years, to be mobilized in considerable force, and kept in camp for some time, so that officers and men learn the actual needs of army life. People will learn by experience, they will not in any other way.

G. H. FULLER, M.D.

DELHI, IOWA, November 30, 1898.

[We gladly give place to this mild remonstrance against too harsh criticism of the War Department in its manage-

ment of the recent war. Exception, however, must be taken to the writer's underlying standard of judgment which plainly worded means that because epidemic diseases have always prevailed in army camps, therefore, they always will and no one is responsible. This is the error that has lain at the bottom of all the difficulty. War is a fiend of destruction, everything is sacrificed with a lavish hand, lives as well as treasure, and because the percentage of deaths from disease is not greater than is borne out by the experience of former wars no blame but only praise is to be ascribed to the management. Must we take no account of the great advance in the knowledge of the etiology of disease and the present advanced position of hygienic and sanitary science? Is it just to compare statistics of a war of aggression against a feeble and bankrupt nation with a great fratricidal conflict in which there was a death grapple for the dearest principle of government?—ED.]

THE COOPERATION OF THE PROFESSION SOLICITED.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—At the last meeting of the American Gynecological Society a committee composed of Drs. Williams of Baltimore, Norris of Philadelphia, Fry of Washington, Reynolds of Boston, and Pryor of New York was appointed to report next May upon the use of antistreptococcic serum in the treatment of puerperal septicemia. We have agreed upon a method of securing the discharges in puerperal cases and upon a standard serum which can readily be procured.

We recommend the use of the serum prepared by the New York City Board of Health. Sterile culture-tubes can be secured from Dr. Torrens, No. 435 Pleasant Avenue, and from Dr. Jeffries, No. 212 East Thirty-fourth Street, New York City. Samples of discharges should be sent to Dr. Jeffries, who will, at the earliest moment, notify by telephone or telegraph the physician attending the case under observation whether streptococci are present or not. In return for this, physicians are requested to furnish some member of the committee with notes of their cases showing at what stage of the disease and in what amounts the serum was used, what general treatment was employed, what local treatment was applied, and the results.

It is desired by the commission to make the report as exhaustive and thorough as possible, and to accomplish the object sought the cooperation of the profession is necessary. We also desire notes of cases in which the serum has not been used. While it is manifestly desirable that one kind of serum be employed in all cases, we will be gratified to receive the results obtained with any which may please the fancy of any particular observer.

In making our report, of course, full credit will be given to each gentleman who favors us with his reports.

Very truly yours,

WM. R. PRYOR, M.D.

NO. 121 EAST THIRTY-EIGHTH STREET,
NEW YORK, November 30, 1898.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

INJECTIONS OF DIPHTHERIA ANTITOXIN FOR SCHOOL CHILDREN—RUSH HOSPITAL FOR CONSUMPTIVES—PERSONAL NOTES—A BILL TO COMPEL INSPECTION OF BODIES BEFORE ISSUING DEATH-CERTIFICATES—DEATH FROM ACETANILID—HEALTH STATISTICS.

PHILADELPHIA, December 6, 1898.

CONSIDERABLE amusement was caused among the profession, and a great deal of unnecessary alarm and worry among the laity, by a newspaper article of last week in which it was stated that public-school children were to be treated with injections of diphtheria antitoxin, the treatment to begin, as a routine practice, next fall. Dr. Charles S. Means, a common councilman of the city, is endeavoring to secure the passage of an ordinance providing that "on and after September 1, 1899, all children in attendance at public schools, shall be immunized for diphtheria by the injection of antitoxin, and further, the Director of Public Safety is directed to instruct the Medical Inspector of the Board of Health to enforce the provisions of this ordinance." Dr. Means was quoted as saying, also, that it is universally conceded by prominent physicians that most persons may be immunized by the injection of antitoxin.

It is by such impracticable suggestions—ignorant is perhaps too severe a word—that the profession is often brought to ridicule. In the first place the cost of the projected scheme would alone be an objection, as immunizing doses of antitoxin, probably in large quantities even, would cost $1.50 to $2 at least. The difficulty of having an injection made by a physician who would not only have to carry an antitoxin syringe, but also a large number of sterile needles or some means of sterilizing one needle after each injection, and the possibility of having abscesses, etc., when so many injections would have to be made in comparative haste, would seem sufficient reason for the abandonment of this scheme. The more important fact, that immunization lasts but four weeks, should prove the utter futility of this measure.

Dr. Means is correct in saying medical men acknowledge the immunizing power of antitoxic serum but he must surely know that all authorities agree that this immunizing period is certainly not longer than a month. Could any one advise a monthly puncture and injection or would any parents permit such measures being carried out? We think not, and it is to be hoped that the matter will sink into the oblivion it deserves until antitoxin immunity can be made to last a year at least, a realization which at present seems far off.

Extensive alterations are to be made to the Rush Hospital for Consumptives, the plans for which have been completed, and the work is to be started at once. The present building, which consists of two parts, one two stories high and the other only one story, is to be made three stories uniformly, which will give necessary room for twenty-eight additional beds.

Dr. Henry A. Saylor, well known in Lehigh County, died last week at his home in Allentown, aged sixty-eight

years. He was very active in politics, and served one term as prothonotary of the county.

The following have been appointed vaccine physicians: Drs. George D. Blomer, Jr., Joseph F. Wallis, Thomas B. Bradley, A. J. Matthews, J. Gilbert Young, J. W. Dubbs, George D. Morton, and George E. Dahis.

Dr. Judson Daland delivered the address before the Harrisburg Academy of Medicine at its third anniversary, and papers are to be read by Drs. W. E. Ashton, H. A. Hare, and John B. Deaver at the eightieth anniversary of the Cumberland County Medical Society of New Jersey.

George F. Edmunds, ex-senator from Vermont, has been elected a member of the Board of Trustees of Jefferson Medical College.

No such law being in effect, it is proposed at the next session of the Legislature to introduce a bill compelling physicians to view bodies and satisfy themselves of death before issuing death-certificates. The reasons given for the necessity of the bill are the prevention of fraud on insurance companies, the prevention of burial during catalepsy, and prevention of crime. It seems hardly necessary to pass such a bill, as any reputable physician who signs a certificate generally knows whether death has occurred and whether it has been natural, and any unscrupulous physician could evade the law under this statute as readily as before it was introduced should he care to. Another measure likely to be introduced is one compelling druggists to label all headache powders or other packages containing coal-tar products, as such. The death of a woman at Pittsburg last week from a headache-powder supposed to contain but 5 grains of acetanilid, has added a new impetus to the movement.

The total number of deaths occurring in Philadelphia for the week ending December 3rd, as reported at the Health Office, was 399, of which 118 occurred in children under five years of age. The total number of new cases of contagious disease was 248, reported as follows: Diphtheria, 114 cases with 35 deaths; scarlet fever, 28 cases with 2 deaths; typhoid fever, 106 cases with 10 deaths.

OUR LONDON LETTER.

[From our Special Correspondent.]

A DISTINCT VARIETY OF HIP-JOINT DISEASE—TRIAL OF THE CHRISTIAN SCIENTISTS IN CONNECTION WITH THE DEATH OF HAROLD FREDERIC—A NEW REMEDY FOR CHRONIC ULCERS.

London, December 1, 1898.

At the meeting of the Medico-Chirurgical Society, held November 22nd, the papers listed for consideration were "A Distinct Variety of Hip-Joint Disease in Children and Young Persons," by Edmund Owen, and "An Improved Method of Treatment of Separation of the Lower Epiphysis of the Femur," by Jonathan Hutchinson, Jr. Following the admirable custom of the London societies, printed abstracts of both papers were placed in the hands of those attending the session, and proof copies of each could be obtained on application at the library. This made the discussion both full and to the point, but had the disadvantage, as at the late meeting of the Gynecological Society, that the second paper was crowded out entirely and its reading postponed to the next meeting. In further contrast to our "eleventh-hour" American methods, papers to be read are in the Secretary's hands months or even a year before they can be reached. It sounded strange to transatlantic ears to hear Mr. Owen, in mentioning the date "last spring" in one of the cases he reported, interject "last spring a year ago, sir; this paper has been here nearly a year!"

The paper was a clear and convincing description of a class of acute suppurative diseases of the hip-joint, quite distinct, and to be carefully separated from tubercular inflammation. The disease is simply an extension of osteomyelitis from the shaft of the femur into the tissues of the epiphysis and epiphyseal line. And as at the hip, unlike any other joint in the body this line is included within the capsular ligament at the joint, the synovia and cartilages become involved. Ordinarily, extension of osteomyelitic inflammation into a joint is extremely rare, but here on account of this curious antatomical arrangement its occurrence is possible and not infrequent. So violent is its action when once it reaches these delicate and actively growing tissues that it is not uncommon in severe or neglected cases to find the epiphysis completely separated from the shaft and the head of the femur lying loose in the acetabulum.

The disease is characterized by sudden, severe pain, rapid rise of temperature, early delirium, and death by septicemia within four or five days, unless the condition is recognized and promptly dealt with. There is often a history of injury or of some systemic disease, both of which probably act by lowering the resisting power of these embryonic tissues and rendering them vulnerable to these infective organisms. It is most liable to be mistaken for acute monarticular rheumatism and usually occurs in children, never after the union of the epiphysis with the shaft in the nineteenth year. The only effective treatment is heroic, opening the joint, removal of the necrosing epiphysis, and thorough washing out of the joint-cavity with solutions of chlorid of zinc or other germicides, followed by drainage. The writer reported four typical cases, three of which had been radically treated, and all recovered with a useful limb, while in the fourth, he incised a peri-articular abscess but hesitated to open the apparently healthy joint. Forty-eight hours later he had to remove a seminecrotic epiphysis, but too late to save the child's life.

Opening the discussion Mr. Barker was glad to hear Mr. Owen distinguish between tubercle and the septic processes; in the one the surgeon could close up the wound, in the others he must leave a drain. Personally, he preferred sterilized saline solution for flushing as being equally cleansing and less liable to depress the vitality of the tissues.

Mr. Golding Bird objected to the wholesale radicalism of the treatment, and reported a case of his own in a boy of eight and one-half years, with typical fulminating symptoms, which recovered completely with a good joint after simply opening the capsule and flushing out the cavity.

Mr. Wallace described a most violent typical case

in a child fifteen months of age, brought into the hospital in a state of coma, with a history of a fall upon the hip a few days before. Upon opening the joint the head of the bone was found not only detached but driven by muscular contraction completely through the softened wall of the acetabulum and lying within the cavity of the pelvis.

MR. MACDONALD related a fatal case in which the joint was not opened during life, but at the autopsy was found full of pus which swarmed with streptococci. Section through the upper end of the bone showed the epiphyseal cartilage healthy and the whole mischief confined to the narrow layer of ossifying cartilage between this and the upper end of the diaphysis.

The President, MR. THOMAS BRYANT, said that in his younger days these cases were seen chiefly in consultation with physicians as suppurative-joint complications following rheumatism, and that before that he had noticed how often the most severe cases of pyemia were those which were accompanied by an abscess in one hip-joint. He saw a typical case only a few months ago which had been mistaken for rheumatism in its first few days, and upon opening the joint found it full of pus. He did not resect but contented himself with drilling through the neck of the bone four or five times, and thoroughly flushing with carbolic solution and draining. He had always found such treatment sufficient and objected to the unnecessary heroicism of resecting in every case.

Mr. Owen, in closing the discussion, replied to Mr. Barker that while he believed sterilized salt solution perfectly satisfactory in tubercular conditions with bacilli of low infective power, yet in these acutely septic organisms he felt safer with active germicides like zinc or mercuric chlorid. He thought the whole pathology of the disease centered round the fact that micro-organisms prefer the delicate, budding tissue of the epiphyseal line, as beautifully demonstrated by Mr. Macdonald, and that this line at the hip happened to be within the joint-capsule. As for the demurs against such radical measures and sacrifice of bone, it was not a question of saving a limb but a life and no half-measures were called for.

The trial of the Christian Scientists for the death of Harold Frederic is now in progress and attracting the keenest attention from all classes. The press comments are surprisingly judicious and show no mercy toward such belated superstitions, especially when the "gifts" are exercised for pecuniary reward. Quite a section of the papers, headed by the erratic *Saturday Review*, is opposing the trial, not from any sympathy with Christian Science, but simply upon the curious ground that Harold Frederic being of age and of sound mind was acting within his rights in risking his own life in any way that he chose. The inalienable right of the adult British subject to make a fool of himself in any way that he pleases, so long as he endangers no one else's safety or comfort, is their plea.

A remedy which is attracting much attention here from its remarkable effects upon chronic ulcers, especially of syphilitic origin, is chinosal. MR. JONATHAN HUTCHISON recently reported a most obstinate case of syphilitic lupus, of three-years' duration, which had resisted the iodids internally and iodoform locally, but which healed in three weeks under chinosal. He said that this was only one of a number of cases in which it had proved most effective in his hands in all forms of tertiary ulcerations.

At the last meeting of the Hunterian Society DR. GLOVER LYON read a paper upon "A New Theory of the Blood-Plasma," which he regarded as made up of minute corpuscular elements given off from the retiform tissue of the intestinal wall. These he regarded as capable of aggregation into the visible blood-plaques, and even corpuscles. This rather startling theory, however, was not supported by any new experimental evidence.

DR. J. H. TARGETT showed specimens from an autopsy upon a child of eleven months which had died of bronchopneumonia, beginning shortly after a sudden attack of choking. Upon section two small corks were found in the stomach, and a larger one one and one-quarter inches long by three-fourths of an inch thick was found embedded in the posterior wall of the pharynx just below the glottis. As the child was insured and its mother had lost five other children of tender years from acute "bowel trouble," all of whom had been insured, there was strong suspicion of foul play, but the coroner's jury could not be brought to think so.

ANOTHER SYPHILIS BACILLUS DISCOVERED — PERICARDITIS IN CHILDHOOD — MINERAL WATERS IN AFFECTIONS OF THE STOMACH AND INTESTINES —A CASE OF RETROPERITONEAL BUBO — RELATIONS BETWEEN THE STOMACH AND DRUGS — IMPLANTATION OF THE URETERS IN THE SIGMOID FLEXURE—SUCCESSFUL REMOVAL OF A RUPTURED SPLEEN.

AT the Berlin Medical Society, October 19th, VAN NIESSEN spoke on "The Etiology of Syphilis." Some years ago he isolated a syphilis bacillus from the blood of syphilitic patients, and from the marrow of the bones of children suffering from congenital syphilis. Later he concluded that the results were untrustworthy, and turned his attention to condylomata, in which he found a bacillus hitherto not described. He tested its effects upon guinea-pigs, swine, and monkeys. In guinea-pigs inoculation produced pustules without suppuration, and indurated lymphatics. The swine in three or four weeks showed multiform exanthemata, and plaques in the throat. The first monkey showed desquamative pustules with sclerosis, and later indolent buboes in the groins and macular pates upon the tail. In the second monkey similar signs developed, followed by total left-sided hemiplegia; the liver was fatty, and there was a focus in the brain. The third monkey died in coma in four weeks. Its liver was fatty, aud there was also peri-arteritis and leptomeningitis. The fourth monkey was attacked with blindness in fourteen days, and paraplegia of the lower extremities. There was a well-marked eruption. It was treated for four weeks by injections of salicylate of mercury, and recovered its sight and a partial use of its limbs.

One week later it died, and the autopsy showed a hemorrhage in the brain, besides fatty degeneration of the liver, and enlargement of various lymphatic glands. Van Niessen concluded from these experiments that he had found the true syphilis bacillus.

BLASCHKO said that so many good observers had attempted without success to find the syphilis bacillus that a report of its discovery must be accepted with hesitation. Van Niessen had neglected to give the details of his investigations, and a person hunting for germs in condylomata might naturally expect to find a variety of them. As only two years had elapsed since the same investigator announced to the world that he had found the true syphilis bacillus, and so soon afterward had admitted that he was mistaken, Blaschko said that one might better wait until his present results were confirmed by others before accepting this bacillus as the true specific agent in syphilis.

LASSAR said that bacteria were present in all early and late lesions of syphilis. He and his assistants had found a great variety of them, but he did not regard any of these as specific. He was sorry that Van Niessen had not showed to the Society some of the pigs and monkeys. From the descriptions given he thought the lesions which had occurred in the later animals were tubercular.

At the session of October 26th, BAGINSKY read a paper on "Pericarditis in Childhood," a disease which is usually considered to be rare, but which investigation had convinced him to be commoner in children than in adults. He had examined sixty cases. In twenty-four of them there was antecedent rheumatism, and in eleven, antecedent tuberculosis. The same forms of pericarditis as occur in adults were found in these children. In the serous form (sixteen cases) the attack began with severe symptoms, an appearance of distress, rapid respiration, high, but irregular temperature, a pulse sometimes small, and rhythmical beating from one hundred and twenty to one hundred and fifty times a minute; sometimes full and of normal rate. The diagnosis is difficult on account of the difficulty in determining the limits of the cardiac area in a child, whose thorax has such a wide range of motion. One should also remember that the area of percussion dulness is different in children and in adults, for the higher position of the diaphragm in a child gives the heart not only a higher position in the chest, but makes it lie more horizontally than in the adult. As a result of this the dulness of the heart area is continuous with that of the liver, and the apex beat is a lateral thrust outward from the median line. For the same reason the position of the heart when the pericardium is filled with fluid changes little with a change in the position of the child's body. The alterations in the area of cardiac dulness do not of themselves serve to make a differential diagnosis between effusion in the pericardium and dilatation of the heart. Of greater importance are the pericardial murmurs, especially those which are heard over the upper part of the heart. Baginsky found in only a few instances the swashing apex murmur which Rosenbach has described as pathognomonic of pericarditis.

In the suppurative form of pericarditis, the diagnosis from physical signs is still more difficult than it is in the serous form, on account of the small amount of exudate. Hence, the necessity of observing the accompanying symptoms with especial care. The temperature changes by bounds, springing from normal to a very high point in a short time. The general symptoms are usually severe. The tuberculous form of the disease is rare and malignant. The most important form of pericarditis is that occurring in connection with polyarticular rheumatism. It is very common and appears early in this trouble. There is often an increase in the size of the heart, and a formation of adhesions between the heart and the pericardium. As the polyarthritis frequently recurs and with it the pericarditis, the pathologic conditions grow worse and worse as years pass. As for treatment the writer obtained good results by the simultaneous administration of digitalis and diuretin, in doses of 60 to 75 grains per day.

AGERON spoke to the Medical Union of Hamburg, October 4th, on "The Use of Mineral Waters in Affections of the Stomach and Intestines." He lamented that the treatment of diseases of the stomach and intestinal tract had not kept pace with the pathology and pathologic physiology of these organs, and that hydrochloric acid and pepsin still formed the chief medicinal treatment of these diseases. The speaker then took up the indications for and against the use of mineral waters, laying stress upon the following points: (1) A knowledge of the composition of a water before prescribing it. (2) A knowledge of its physiologic and pharmaco-dynamic power. (3) A knowledge of the dietetic conditions under which such a water can work efficiently. (4) An exact diagnosis of the pathologic conditions in the case in hand, according to the modern improved methods of making it.

At the session of October 18th, JESSEN reported a case of "Retroperitoneal Bubo," occurring in a man aged thirty-eight years, and accompanied by high fever, and a moderate amount of swelling in the inguinal glands. There was also enlargement of the spleen, contraction of the psoas muscle, and pain in the region of the left kidney. The trouble was at first thought to be either leukemic or pseudoleukemic. Gradually the swelling increased in the left flank and fluctuation could be made out. An incision gave vent to a great amount of pus, the cavity extending well forward of the kidney. The recovery, which was slow, was uneventful. Fourteen days before his admission to the hospital the patient suffered from three soft chancres and six days later developed fever. The infection from these was thought to have extended first to the inguinal glands and also to the retroperitoneal glands in the region of the kidney.

At the Medical Union in Munich, October 12th, MORITZ spoke of the "Relations between the Stomach and Drugs." There is a great difference in the time of absorption of different fluids from the stomach. Water takes less time than acid solutions, carbonated waters, soup, etc. A pint of water will leave an empty stomach in thirty to forty-five minutes. If a roll is eaten before the water is drunk, the time for absorption will be materially lengthened. A soluble powder will be absorbed

more quickly if taken with water than if taken without. Medicines taken with milk or soup remain longer in the stomach than when taken with water. Resorption is still slower if a meal precedes their administration. Thus, 5 grains of salicylate of soda were absorbed from an empty stomach in half an hour. When taken after a meal there was still a considerable part of the dose remaining at the end of an hour. As a result of these principles the effect of some medicines is different when taking fasting, from that observed when they are taken on a full stomach. Attempts to make a medicine pass through the stomach in insoluble capsules have best succeeded when glutoid has been used as a protective. Gruel made from oatmeal or wheat meal has also a considerable protective action, and it is a real help to give medicines which upset the stomach, such as arsenic or digitalis, in a vehicle of this kind. If it is desired to increase the absorptive power of the stomach it is only necessary to add twenty-per-cent. alcohol, or some irritant to the medicine.

FRANK showed a sixteen-year-old boy to the Imperio-Royal Society of Physicians of Vienna, October 21st, upon whom he had operated for ectopia vesicæ. The ureters, with a portion of the bladder-wall, were implanted in the sigmoid flexure. For twenty days a drain was kept in the rectum which, by a sort of siphon action, kept the patient from getting wet. By that time he had learned to control the escape of water from his rectum, so that he could go for one or two hours, or even longer, without emptying the viscus. In the night he was not awakened by the necessity of evacuation.

EWALD reported a similar operation performed upon a five-year-old boy, with an equally good result. Maydl used to say that this operation should not be performed before the tenth year, but he had carried it out with success upon a patient only three years of age. On account of the thin walls of the ureters, and the fact that the bladder was in part present, the operation was a particularly difficult one. The siphon-drainage recommended by Frank did not succeed in keeping this patient dry.

SCHNITZLER had twice implanted the ureters in the sigmoid or the colon; once for a vaginal fistula, and once for a carcinoma which had broken through into the bladder. The latter patient was in good general condition, and threatened suicide on account of her distressing urinary condition, and he, therefore, thought that it was justifiable to make an attempt to relieve her. One ureter was implanted in the ascending, and the other in the descending, colon. The patient died from the effects of the operation, and the autopsy showed necrotic areas in the mucous membrane of the colon, set up, it was thought, by a preexisting pyelitis.

SAVOR showed a ruptured spleen which he had removed from a woman in the sixth month of pregnancy. The rupture was a multiple one, and had been caused by a kick. There was little shock, but as the condition upon the following day showed internal hemorrhage, the abdomen was opened. The uterus was found to be in perfect condition, the injury being confined to the spleen, which was removed. The patient did not abort, and made a slow but complete recovery. This is the ninth recorded case of removal of a ruptured spleen, six of the patients so operated upon having recovered. The prognosis is far better when the rupture is not immediately due to the trauma, but is the result, as it was in this case of the distention caused by a subcapsular hematoma.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.—SECTION ON GENERAL MEDICINE.

Stated Meeting, Held Tuesday, November 15, 1898.

DR. LOUIS FAUGERES BISHOP in the Chair.

DR. WM. N. HUBBARD, the secretary, read for Dr. George Roe Lockwood of New York, who was unavoidably absent, a paper, entitled

THE NON-MEDICINAL TREATMENT OF HABITUAL CONSTIPATION (see page 741).

This was followed by a paper by DR. JUDSON DALAND of Philadelphia on

CONSTIPATION AS A CAUSE OF ANEMIA AND CHLOROSIS.

Scarcely anything, of course, can be added to Sir Andrew Clarke's classical work on the connection between constipation and chlorosis. The subject needs to be dwelt on, however, to bring home its lessons practically. Besides the general effect of constipation on the blood in the production of anemic conditions it still furnishes excellent opportunities for study. It is especially to be remembered that though stools may be regular constipation may exist. A patient who should pass six to seven ounces of feces, for example, may pass but five or six, so that accumulation of fecal material may occur despite regular stools. It is the effect of the toxins absorbed from this accumulated feces that is to be feared. In atonic constipation, despite regular stools, we may be able to wash scybalous masses out of the intestine that show by their form that they have been molded in the intestines perhaps by weeks of retention.

Dr. Daland then detailed two cases of chronic constipation with an associated chlorotic blood-condition as types of the blood-changes due to the toxemia incident to constipation. One was that of a child of twenty months, where all the blood-symptoms of pernicious anemia were present. Only the disproportionate decrease of the hemoglobin in successive blood-examinations had revealed the fact that it was a chlorotic condition.

In all intestinal trouble these blood-changes are liable to occur. They complicate especially typhoid fever and much can be done for them if properly recognized. Many general disturbed conditions of the system are associated with intestinal trouble and these blood-changes. Biliousness, so called, and analogous conditions are undoubtedly influenced by such factors.

Dr. Daland commends for these conditions especially high large injections of saline solution. The whole colon may thus be flushed and his experience on Swinburne Island during the last cholera scare showed him that at

times even the ileocecal valve could be passed and the small intestine flushed out in this way.

In the discussion, DR. BEVERLEY ROBINSON said that prophylaxis is an important element to be considered in the matter of constipation. Mothers are to blame for not insisting especially that their daughters should learn regular habits in the matter of the evacuation of their bowels. The neglect of this undoubtedly has most serious consequences. From the indifference springs evil habits and untold evil. In seven out of ten cases the supposed uterine troubles, the persistent headaches, the chlorosis, the nervousness of women arises from the neglect of the bowel movements. Society's conventions are against the formation of regular habits in the matter. Civilization is to blame in certain respects. In New York there is practically no place where women may go if for any reason they have not been able to fulfil the function at a regular time. It is a shame that it is so. Other cities, notably Paris, have very laudably provided for such necessities of nature and New York certainly should be stirred up in the matter. Still another source of constipation is the use of all sorts of patent nostrums to secure a movement of the bowels until finally a condition of non-irritability develops and makes the subject most difficult to treat. Often these proprietary purgatives act for the time being at least as well and sometimes better than the regular prescriptions, but the inevitable result of using purgatives habitually asserts itself sooner or later. As to chlorosis and constipation he had seen constipation without chlorosis and chlorosis without constipation. There is a certain amount of interdependence between the affections though it does not seem in his experience as much as is often claimed.

DR. VAN VALZAH thinks the treatment should be more specific. He considers that the most important thing in the treatment of constipation is the recognition of its cause. This is often in the stomach. In thirty cases examined chemically by him recently he found absence of all stomach secretion though absolutely no symptom pointing to stomach trouble had been complained of. There was only diarrhea, and no wonder, since food was being passed on to the intestines in an absolutely unprepared state. Hypersecretion, especially hyperchlorhydria, led to constipation. For these cases Carlsbad salts is the very best remedy. They are purgative and also alkaline, and used for two or three weeks they give excellent results. Milk of magnesia is the next best remedy, and calcined magnesia might be employed with good results at times. Myasthenia of the stomach with failure of motility and dilatation, indicated by the well-known splashing sounds, is often accompanied by myasthenia of the bowels. In these relaxed conditions with muscular degeneration there must be no laxatives used; they will only make matters worse; tonic, not irritant treatment, is required. After the stomach the liver should be thought of. If the stools are pale in color calomel in minute doses should be given: $\frac{1}{15}$ or $\frac{1}{16}$ of a grain frequently repeated. When the trouble is in the small intestine the prominent symptoms are an increase of gas, a burning feeling, a sense of unrest, of oppression referred to the abdomen, and finally the presence of indican in the urine. This last is important. Water he thought of the greatest importance. Not enough water is drunk, especially in the cities, and two to six glasses of it should be prescribed between meals. This is often enough of itself to overcome the tendency to constipation. Of drugs he had found that rhubarb gives good results and does as little harm as possible. In myasthenic states particularly the tannic acid of the rhubarb tones up the muscular coat of the intestines. Of course it should not be given to such an extent as to produce loose stools as it will then inevitably be followed by constipation.

In spasmodic states of the intestine, of which ribbony stools is the pronounced symptom, some of the antispasmodics are to be used, for instance, hyoscyamus in large doses, 1 to 1½ grains or even to the production of slight toxic symptoms. Cascara, when properly employed is an invaluable drug. Every one should have some fixed time when they go to stool. This should be when they are at leisure. It may be any time, morning, noon, or night. The cascara should be given not three times a day as is often done, but in one dose so as to act at the desired time. The fluid extract of Parke, Davis, & Co. has given him the best satisfaction. The dose must be decided for each patient and must be just enough to produce a formed not a loose stool. After ten days to two weeks the dose may be lessened by a drop or so every third night, not oftener, and thus the patient gradually brought to do without its assistance.

As to fruit it does good so long as it does not increase gas formation, or produce burning feelings or diarrhea. If it occasions any of these symptoms it is not doing good.

DR. L. EMMET HOLT said that in children the conditions leading to constipation are, in contradistinction to what obtains in adults, comparatively simple. The first thing to do is to find out the entire daily routine of the child. Usually there is some fault of regimen. Correct that and the trouble ceases. The nurse is mostly at fault and a good nurse seldom has a constipated child to care for. In his own children he has often noticed this fact and without a careful nurse drugs and directions for diet, bathing, and massage often fail of any lasting effect. At times there is too little residue left from the child's food and then this must be corrected. Usually all the ingredients need to be increased, not the fats alone, because this will almost invariably lead to dyspepsia and increase the constipation. During the summer, while in the mountains, he saw a man who had himself been greatly helped by his morning cold plunge take his nursing baby down to the lake (water at 70°) and give it a short plunge-bath with excellent results as regards constipation. As for drugs cascara is undoubtedly the best, while suppositories are of great value in producing a movement at a given time in order to create the habit.

DR. JACKSON considers that the most important factor for treatment is the decision of the question as to which class of constipation the patient has. Is it due to abnormal conditions of the digestive tract or is it functional and due to the patient's general condition?

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIII. NEW YORK, SATURDAY, DECEMBER 17, 1898. NO. 25.

ORIGINAL ARTICLES.

CAMPHORATED TINCTURE OF OPIUM IN CUBAN MALARIA, MIXED MALARIA, AND TYPHOID-FEVER INFECTION.[1]

BY W. H. THOMSON, M.D.,
OF NEW YORK;
PHYSICIAN TO THE ROOSEVELT HOSPITAL.

AT the beginning of my service at the Roosevelt Hospital on the first day of September, last, I found in my wards 61 cases of Cuban malarial fever in soldiers who had contracted the disease at Santiago. The majority of them had been in the hospital from August 17th. The duration of their illness before coming to the Roosevelt Hospital had ranged between 20 and 40 days. In all instances they had been treated first with quinin, and in a large proportion this had been supplemented by free dosing with Warburg's tincture, and with arsenic.

Subsequent to September 1st and extending to October 20th, 39 additional cases were admitted, making 100 in all, besides a group of mixed malarial and typhoid-fever cases, to be referred to later. Of this list 63 were actively febrile, the temperature ranging from 103° to 107° F. Of these 40 per cent. had chills, with the usual succession of symptoms, but with true intermissions in only 10 per cent. The chills were irregular rather than periodical in the remaining 30 per cent. They seemed in some cases to be double tertian and in some double quartan, but it was difficult to settle this fact conclusively in any of them, as the paroxysms of rigors were very irregular. The remaining 60 per cent. of the febrile patients had no chills, and the course of the fever in them was very variable, the temperature range rising and falling with such irregularity that the curves on the charts were in this respect characteristic of the affection and in marked contrast with those of typhoid fever.

The plasmodium malariæ was found in 90 per cent. of all the cases, in some, however, not until after repeated examinations. The commonest forms were crescentic. Some patients showed relatively large crescents, and some small. These crescents were often very numerous, occasionally markedly so in groups of patients who had been admitted together, as if they had been equally exposed to the same infection. Besides the crescents there were many actively motile extracellular bodies visible which were very small and round in contour. Masses of free pigment were often seen in the field as well as in the white corpuscles. Only one definite separate flagellum was detected, but more might have been found but for press of time.

In their clinical features the most pronounced effect on the patients of the infection was anemia, with emaciation, often extreme. The impoverishment of the blood seemed to be progressive, for it continued in many of the afebrile cases, much as it does in patients with pernicious anemia without febrile paroxysms. The anemia also appeared to be quite independent of enlargement of the liver or spleen. The liver was noted as enlarged in not more than five per cent. The spleen was enlarged in about fifty per cent.

In the great majority of the patients when they were running an actively febrile temperature there was no delirium, but instead a characteristic taciturnity, all questions being answered correctly, but slowly and in monosyllables, the patients remaining wholly apathetic and indifferent to their surroundings. It was upon this particular symptom that the effect of a special medicinal treatment to be mentioned presently was most marked.

After admission to the hospital some 65 of these patients were treated for fourteen days by careful feeding and nursing, in hopes that the change from camp and transport conditions would of itself be beneficial, and, along with this, quinin in doses of from 30 to 60 grains a day was administered, or Warburg's tincture in ½-ounce doses three times a day, while others were treated with arsenic, either alone or added to the other drugs. The general results, however, had been unsatisfactory. In some cases the quinin held the temperature for a few days, but only to be followed by relapses. Its best results were in the small number of patients who showed periodical remissions. Warburg's tincture seemed to be more successful than quinin, but arsenic, though pushed to the production of digestive disturbances, appeared to be of very doubtful effect. Cold baths were used for six patients with high temperatures, but they did not bear the baths well, while the course of the fever not being modified thereby, the baths were abandoned.

The report of this experience of two weeks in the management of these patients led me to try a modi-

[1] Read before the Medical Society of the County of New York, November 28, 1898. For discussion see page 813.

fication of treatment as follows: Fifteen grains of quinin with 15 grains of powdered ginger were administered twice a day, once in the forenoon and once in the afternoon, with ½ an ounce of the camphorated tincture of opium, and a like dose of the latter without quinin at 10 P.M. An ounce and a half of paregoric, equal to 3 grains of opium, was thus taken daily. All the patients with whom this was first tried, 47 in number, were actively febrile, 84 per cent. of them severely so. In order, however, to test comparatively the effect of this medication 14 febrile cases, of whom 65 per cent. were severe, were treated with Warburg's tincture alone, as controls.

The results were as follows: In 22, or 47 per cent., of the number who took paregoric the result was an immediate break in the fever, that is, the temperature fell to normal within 24 hours, nor did it rise again afterward. This effect was the more impressive because in every instance they had been unavailingly treated for an average period of ten days previously without reducing the fever. The treatment was then continued from 7 to 14 days when the men were discharged. Under this heading of reduction of temperature in 24 hours, were 5 patients who had been treated exclusively by large doses of Warburg's tincture without its affecting the temperature. Of the remaining 25 out of the 47, there were ten patients, or about 21 per cent., in whom it took from 36 to 48 hours to reduce the temperature to normal. Of the remaining 15, there were 3 in whom this treatment failed to control the temperature. One of these, however, had a severe chronic colitis, to which his moderate but long-continued fever seemed to be mainly due.

No relapse was recorded in the case of any patient who took the paregoric treatment after the temperature was once reduced to normal. In 1 case it took 3 days before the temperature became normal. Previously, the patient had not been affected by Warburg's tincture. In 5 cases, or 10.6 per cent., the paregoric treatment could not be continued on account of its causing nausea. These patients were then treated by the above doses of quinin and ginger alone, with a relatively slow recovery, except in 1 case which soon yielded to a third dose added to the usual prescription.

The remaining 6 cases out of the 47 proved in time to be cases of mixed infection of malarial and typhoid fever. The differential diagnosis in these patients was at first difficult, but in time was readily demonstrated. Other than among the 5 above mentioned, who could not take the paregoric without vomiting, there were only 2 patients who showed any of the ordinary symptoms of opiates. The remainder had no narcotic symptoms whatever, but quite the reverse, the paregoric seeming to raise them out of their stupor, and the patients almost invariably spoke of their feeling generally much better and stronger immediately after taking it.

To compare now the 14 cases treated with Warburg's tincture: In 2 patients, or 15 per cent., the temperature was reduced in 24 hours. These were both recently admitted patients who previously had been treated with quinin. In 12, or 85 per cent., it took from 48 hours to 10 days to break the fever. Besides these, there were 7 cases in which the Warburg tincture failed to break the fever after 10-days' treatment, though as some of these patients also took quinin they are not included among those who were put on the Warburg tincture alone, as control cases. All of these 7 patients recovered in from 24 to 48 hours under the paregoric treatment after it was adopted with them. Of the remaining 39 out of the total of 100 patients, 26 were admitted as convalescents without any fever. They were, however, in a very reduced state, the greater number being very anemic, and the plasmodium malariæ was found in 80 per cent. of them, often in as large a proportion as in the febrile patients. They were all treated with the paregoric, quinin, and ginger, the same as the febrile patients, with apparently just the same beneficial results, as appears in the following summary of the general effects:

Of the 47 above-mentioned patients treated with paregoric the general condition upon admission was reported as "very weak" in 17, or 38 per cent.; as "weak" in 10, or about 21 per cent.; as "fair" in 20, or nearly 43 per cent. Of these 3 classes, the effect of the paregoric treatment upon the 17 very weak patients is noted as "excellent" in 13, or 76 per cent.; as "fair" in 3, and as "negative" in 1. Among the 10 classified as weak, it is reported "excellent" in 7; "good" in 2, and "negative" in 1. Among the 20 classified as in fair condition when admitted, the effect is reported as "good" in all, with one exception in which it failed to reduce the temperature. Of the 39 afebrile patients admitted as convalescents, about 38 per cent. were in a very weak state. All of these had been treated previously with iron, and some with arsenic as well, for their extreme anemia. Several of these patients were delirious on admission, and it was in them especially that the paregoric seemed to act most promptly in restoring the mental equilibrium and in improving the appetite. In only 4 of the 39 was it reported that they were unable to take the paregoric with benefit. While taking the paregoric they were treated for the anemia with a pill of 2 grains of iron sulphate, 2 of

black pepper, and 1 grain of powdered nux vomica. Among the 14 cases treated exclusively with Warburg's tincture, 2 were classified as "very weak," 5 as "weak," and 7 as "fair." Both the 2 very weak, and the 5 weak patients, were not improved in their general condition at all, and of the 7 in fair condition at the commencement, 2 were made worse and 5 made a fair recovery.

From both the blood examinations and the clinical features of the fever, it is evident that the Cuban malarial parasite with which we had to deal belonged to the estivo-autumnal type, and that its cycle of development in the blood was very irregular in time, so that a corresponding irregularity resulted in the febrile reaction connected with the times of sporulation of the parasite. This would seem to indicate that the specific action of quinin, so well marked in our American tertian and quartan fevers, is best secured during the afebrile periods, or only at certain stages in the life history of the parasite, but that in the more or less continuous forms of malarial fever it loses much of its effect. The only patients among our present group in whom quinin was singly effective were those, as above-mentioned, who had definite intermissions. When, therefore, we have to deal with an infection which does not afford us any regular intermissions the action of quinin is still valuable, but it greatly needs to be supplemented by other remedies. Increasing the doses of quinin in such patients does no good whatever. One patient stated that he took 40-grain doses three times a day, and thought that it made him a great deal worse.

It has been a matter of common experience, especially in the treatment of malarial fevers in the tropics, that the action of quinin appears to be promoted by the simultaneous administration of various spices. The remarkable farrago of compounds in Warburg's tincture, the original formula of which is said to have contained 76 ingredients, powdered snake skins among the rest, doubtless owes much of its efficiency in chronic malarial disorders to its predominant proportion of spices. I have been accustomed, therefore, for many years to prescribe powdered ginger along with quinin, in equal quantities, and I have felt convinced that I can get along with smaller doses of the quinin itself by adding the ginger, in the treatment of our ordinary intermittents. In a number of cases I add pulverized capsicum, 1 grain to 4 of quinin. I have known ginger alone, administered in free doses in hot milk to break up chronic ague of the quartan type, when quinin had conspicuously failed.

Opium is one of the most ancient of remedies in the treatment of malarial fevers, as it was largely used by both the Greek and the Roman physicians. It maintained its position quite down to the period of the introduction of Peruvian bark, and afterward. In the Seventeenth and Eighteenth Centuries it was often prescribed in full doses, generally in tincture form, taken about an hour before the expected paroxysm. In this century it was highly praised by Lind in England, and by Dickson of South Carolina, to break up the cold stage, and Dickson cites approvingly its employment by a number of physicians in our Southern States in the treatment of their so-called bilious remittent fevers, in combination with camphor, administered every three or four hours.

It is interesting to note in this connection some of the conclusions of the British Royal Commission appointed to investigate the opium question in India in the years 1893–94. In this voluminous report of the testimony of 900 persons, in reply to 28,000 questions propounded by the Commission, a large majority of the replies were in favor of the use of opium as a prophylactic and antidote to malarial fever in India. Sir William Roberts, the well known medical author, who served upon this commission, in a paper read by him as President of the Section on Pharmacology and Therapeutics of the British Medical Association, in 1895, maintains that the antimalarial properties of opium are due to its alkaloid, commonly named narcotin, but which he claims should be termed anarcotin, as it has neither anodyne nor narcotic properties, but acts instead as an antiperiodic. The proportions of the two alkaloids in Smyrna opium are: morphin, 8 per cent.; anarcotin, 2 per cent.; while in Bengal or India opium the proportion is morphin, 4 per cent., and anarcotin 6 per cent. Anarcotin, as an antiperiodic, was brought to the notice of the Indian Government fifty years ago as a substitute for the then scarce and expensive quinin by Sir William O'Shaughnessy, 1838, who reported 138 cases of intermittent and remittent fevers treated with it with 65 per cent. of cures. These results, and others of like character, induced the Indian authorities to institute further experiments, and these proving favorable, they caused anarcotin to be prepared in quantity at the laboratories of Ghazipur and Patna, and distributed to the medical depots throughout India. Sir William Roberts then cites two communications on the antiperiodic powers of anarcotin which are based upon a large experience, and claims that they prove incontestably that anarcotin is scarcely inferior, and in some classes of cases is superior, to quinin. The first communication from Dr. Palmer reports the results in 980 patients treated by doses of from 1 to 3 grains of anarcotin. He states that in 70 per cent. the fever was aborted at the second paroxysm

after the medicine was administered, in 20 per cent. the arrest was equally sure, but was not quite so quick, and in 10 per cent. the remedy failed. He further remarks that there are cases in which anarcotin is decidedly more efficacious than quinin, when quinin has been given for a long time without effect. The second report from Dr. Garden on the use of anarcotin in 684 cases of malarial fever in the same district is very much the same as that of Dr. Palmer.

Whether the beneficial effects of the camphorated tincture of opium in the cases included in my report were due to an ingredient of opium capable of acting directly upon the plasmodium malariæ as quinin does, I am not prepared to say. I am rather inclined to the opinion myself that the opiate acted as a stimulant which enabled the system to cope better with the malarial toxemia, and on that account I chose the camphorated tincture in preference to any other preparation of opium on account of its more pronounced stimulating properties due to the addition in the preparation of camphor, benzoic acid, oil of anis, and alcohol. However that may be, the effects of this preparation were in the great majority, as above noted, the very reverse of narcotic, and more like those of both a cardiac and general nervous stimulant.

With reference to the cases of mixed infection of malarial and typhoid fever there were six instances. All of the patients had a history of malarial fever previous to the development of the symptoms of typhoid fever, and in each of them the plasmodium malariæ was found on admission to the hospital. They all ran the usual course of typhoid fever, and in four of them the plasmodium had entirely disappeared from the blood when they became convalescent. The typhoid fever itself was treated according to our ordinary hospital treatment without any quinin throughout. In 2 cases, however, after the patients seemed to be fairly convalescent from typhoid fever, they were attacked with chills and sharp rises of temperature, and with a reappearance of the plasmodium in the blood. However, these soon yielded to the quinin and ginger treatment without paregoric.

Besides these we had 33 cases of typhoid fever in soldiers, 20 from Chickamauga Camp, 8 from Montauk, 2 from Jacksonville, 1 from Tampa, 1 from Santiago, 1 from Thomasville. Of these, 18 were registered as "severe" cases, 6 as "fair," and 9 as "mild." They all recovered except 3, 1 from Jacksonville, 1 from Chickamauga, and 1 from Montauk, whose cases were interesting from the fact that all 3 succumbed while they were apparently convalescing from intestinal perforation. As this is a rare accident, occurring only once in 150 consecutive cases at the Roosevelt Hospital, and here we had 3 cases in the first 27 soldier cases admitted, their histories were investigated, with the result that all 3 had refused to go to their regimental hospitals when they first became ill, preferring to report at drill instead, until they were prostrated by weakness. This record serves to illustrate the danger of walking about while a condition of ulceration is present in the intestine. In 2 of these patients laparotomy was performed by my colleague, Dr. Abbe, as soon as possible after the onset of the symptoms of perforation. The seat of the lesion was found in each, and the intestine resected. One of the men lived 24 hours after the operation, and the other five days.

Besides the 33 soldiers with typhoid, we had 32 other cases of this fever at Roosevelt during the months of September and October, admitted from the city, of whom 18 were males and 14 females. Of these 32 patients, one died, but he was far advanced in the disease, and in a serious condition at the time of his admission to the hospital. I beg leave, therefore, in conclusion, to make a reference to two measures of treatment which I adopted, which may be of interest. Twelve patients were given cold baths with salts and carbonic acid, in imitation of the Nauheim baths, obtained from the Triton Company of Cliff street. The temperature-charts of twelve other patients, as near as possible like them in condition, and at the same fever stage, to whom the ordinary cold baths were administered, were used for comparison. In every instance the effect of the cold Nauheim baths was to lower the temperature for a longer time than the corresponding simple cold-water baths in the control cases. In other respects the effect seemed also favorable, the stimulating cutaneous impression of the carbonic acid appearing to counteract the depression of the cold, though for a time the nurses complained of the prickling of their hands from the gas and the salts.

My second observation is in reference to increasing the elimination of toxic ingredients from the blood in the urine by the diuretic effects of intestinal lavage with normal salt solution. The amount of urine passed in the 24 hours was first measured for two days, and then lavage was employed once a day at 4.30 P.M., with six pints of normal salt solution at a temperature of 104° F., administered by Kemps' rectal irrigator. This was employed in 9 cases. The amount of fluids taken by mouth by the patients was also measured during the 48 hours before commencing the lavage, and they were not allowed to take any greater quantity of fluids daily during the treatment. The result was that in 7 cases the urine was increased from 10 to 20 ounces daily. In 1 case, seen in consultation in private practice, in which

there was albumin in the urine, and the amount passed in 24 hours was only 20 ounces, after the lavage it rose to 48 ounces daily, and the albumin disappeared. There could be no question also that the general symptoms of these patients markedly improved at the same time, but the number is too small to base permanent conclusions upon this measure, though sufficient to encourage further trial. In 1 case it had to be intermitted on account of hemorrhage, and in 1 patient, who was suffering from a relapse, it seemed to be of no particular benefit. The theory on which this procedure is based is that as the greatly increased toxicity of the urine in typhoid fever has been fully demonstrated as following upon a cold bath, so whatever increases urinary elimination may be regarded as contributing to free the blood of toxins. That intestinal irrigation with hot saline water does have a positive diuretic effect I have seen demonstrated often in other conditions, and hence I believe that it may be of service in the management of this particular fever.

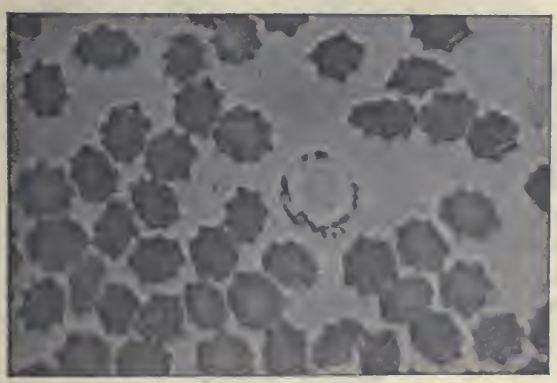
THE CUBAN FEVER PLASMODIUM.[1]

BY ROBERT L. WATKINS, M.D.,
OF NEW YORK.

BEFORE showing you the plasmodium of Cuban fever, I will first throw on the screen a photograph of the spherical form of the hematozoa more observed some years ago than at present perhaps.

Next I show you the spherical form found in a specimen of blood taken from a negro off the Gold Coast of Africa and sent to me by Dr. Hall of London some years ago. The blood was some six weeks

FIG. 1.

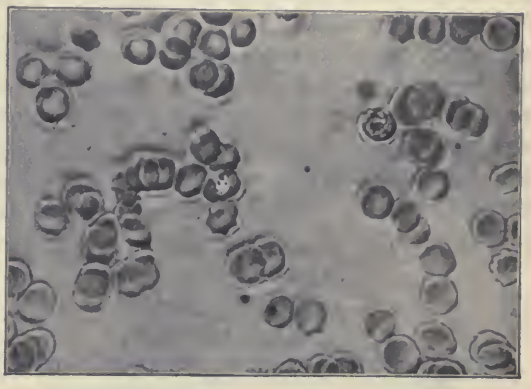


Melaniferous leucocyte described by Laveran.

coming, yet when it arrived this form of Laveran's plasmodium was found in the specimen, as well as that of the *spirochotæ* of Obermier and which I have not time to show you. The next is the melaniferous leucocyte as Laveran describes it ($\frac{1}{10}$ Zeiss objective), taken from one of two men who had been in Central Africa (Fig. 1).

Now that you have renewed your familiarity with the shape of the plasmodium, I next call to your notice the blood of a Santiago soldier (Fig. 2).

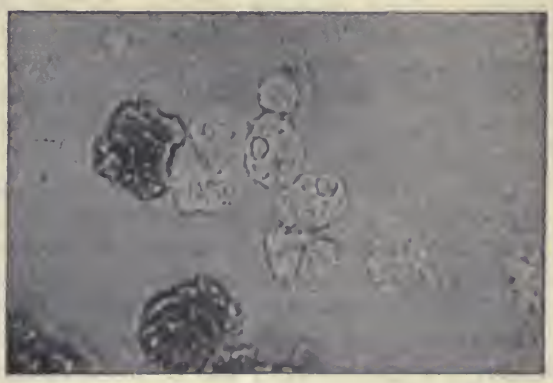
FIG. 2.



Plasmodium present in the blood of a man ill with Cuban malarial fever.

This man, aged twenty-four years, was not sick until he reached home in August. He was then taken with fever and chilliness, but no real chill, the fever fluctuating from 102° to 104° F. and back to normal, irregularly. He had diarrhea, cough, expectoration, and emaciation to such an extent that some of his friends feared consumption. He was, of course, very yellow like the rest; but very little pigment was found in his blood. He was placed on 4 grains of quinin 4 times a day and slowly got better. He was

FIG. 3.



Specimen from a malarial patient at the New York Polyclinic shows the segments of the plasmodium being absorbed and carried away by leucocytes. Fibrin here is also very distinct.

on quinin when this photograph was taken. The germ is of the irregular form of the estivo-autumnal type and, according to Thayer's plates, would come under the head of circular pigment clumps or the pre-

[1] Stereopticon exhibition before the Medical Society of the County of New York, November 28, 1898.

segmenting, the fever of which, according to Osler, is irregular.

Dr. Orin Andrews of Gardner, Mass., whose patient this was, writes me that this man was taken with typhoid fever October 1st, with the characteristic symptoms of intestinal hemorrhage, epistaxis, and rose spots.

The next specimen (Fig. 3) shows the condition of the blood of a malarial patient at the New York Polyclinic Dispensary. He had irregular chills, and at the time the photograph was taken his temperature was 102° F. He was given 4 grains of quinin three times a day. The broken segments in the white cells can be seen quite plainly. Some have been partially absorbed, and therefore are not distinctly outlined.

COMPARATIVE MORPHOLOGY OF MALARIAL PLASMODIA.[1]

BY JAMES EWING, M.D.,
OF NEW YORK.

The Tertian Parasite.—The earliest form of the tertian parasite appears in the stained specimen as a spheroidal or irregularly-shaped, unpigmented body, staining densely, but somewhat unevenly. These bodies are indistinguishable from similar forms of other varieties of parasites. The earliest form of the parasite distinguishable as belonging to the tertian type is an irregular ring-shaped body, exhibiting a distinct achromatic spot, and occasionally a few fine grains of pigment. The red cell is then somewhat swollen.

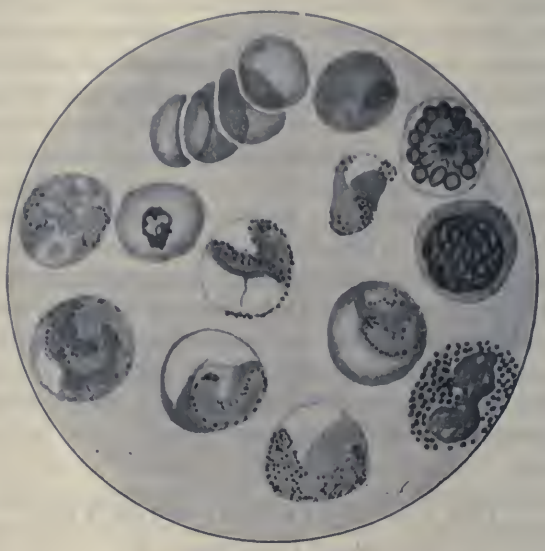
The later stages of the tertian parasite appear in stained specimens as bluish-colored bodies of very irregular shape, depending on the activity of the ameboid motion at the moment the cell dries. The pigment deposit gradually increases, the diameter of the swollen cell enlarges, and the loss of hemoglobin is usually marked.

The body of the parasite stains uniformly bluish, no reticulum being usually visible, although the achromatic spot gradually increases in size.

In the presegmenting forms the body of the parasite exhibits a distinct, deeply-stained reticular structure. The achromatic substance appears to subdivide, and many clear areas appear in the meshes of the reticulum.

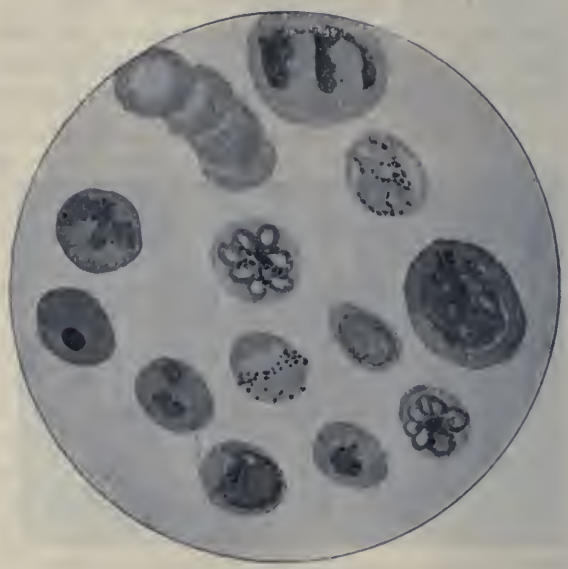
In the segmenting tertian body the pigment is usually, but not always, gathered in the center of the rosette. The reticulum having deepened, the meshes become rounded, and finally break up into fifteen or twenty spores, each enclosing a portion of the achromatic substance. With the rupture of the red cell the new spores and pigment are discharged into the plasma, at the time of the paroxysm. The spores soon enter new red cells, while the pigment is carried to the internal organs, principally the marrow, spleen, and liver, and there englobed by phagocytes. The pigment of the tertian parasite is very fine in the early stages of the organism, increasing in coarseness with its further development, and in the segmenting bodies, coarse blocks may be found.

FIG. 1.



The tertian parasite.

FIG. 2.



The quartan parasite.

The Quartan Parasite.—The quartan parasite is very similar in morphology to the tertian organism. In all except the earliest stages it may be distinguished from the tertian parasite by its higher refractive quality and more sluggish ameboid motion

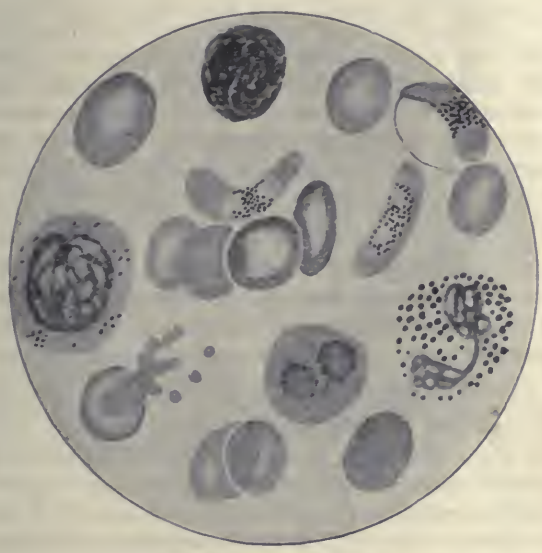
[1] Drawings made and contributed to the MEDICAL NEWS by special request.

in fresh specimens, and by the shrinkage of the cell and presence of coarse pigment grains as seen in stained specimens.

The quartan rosette is very characteristic, and being usually present in the circulation in considerable numbers furnishes the most reliable evidence on which the quartan parasite may be identified. The quartan rosette is smaller than the tertian form, the cell is shrunken but not decolorized, the pigment is coarse and often radially grouped, while the spores number only seven to twelve.

The Estivo-autumnal Parasite.—The estivo-autumnal parasite, or the malignant tertian of Italian writers, is first seen in the red cell, or plasma, as a minute spheroidal body, usually appearing slightly vesicular in stained specimens. Very soon the

Fig. 3.

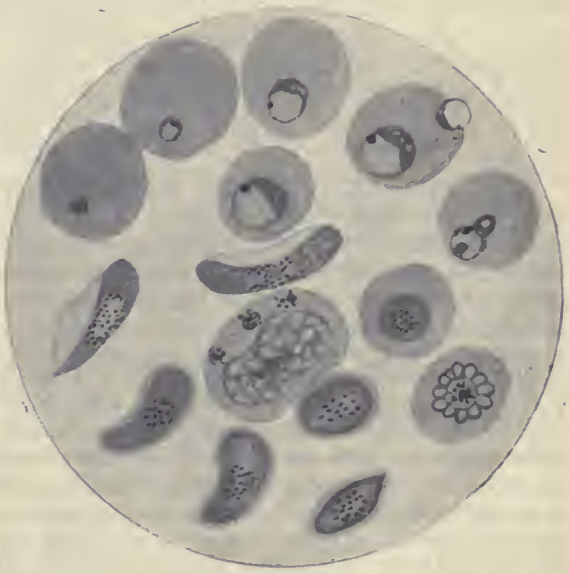


The estivo-autumnal parasite.

spheroidal body becomes distinctly vesicular and usually a densely staining point may be distinguished. Very soon after infection the red cell begins to shrink, but its decolorization proceeds slowly. After a few hours the very characteristic "signet-ring" form of the parasite is found in the red cell. The ring, in properly fixed and stained specimens, is very regular in outline. About one-fourth or one-third of the circumference exhibits a marked thickening, recalling the seal of a ring, while the bow of the ring is extremely fine and geometrically circular. At a variable point in the ring a densely staining point may usually be seen, and in many specimens one or more minute achromatic spots may be distinguished. Double infection of the cell is not uncommon, and occasionally the ring appears to be attached to the surface of the cell, or the bow may project beyond the edge of the cell. Occasionally there is an ingrowth of the parasite from the bow of the ring, but the further development of this peculiar body usually proceeds in the viscera only and cannot be followed in the peripheral blood. In marrow-smears, the body which appears to form the next developmental stage of the ring appears as a distinctly spheroidal parasite, staining deep blue in its peripheral and much lighter in its central portions. It usually occupies about one-half the diameter of the shrunken cell.

While the ring forms of the Cuban malarial parasite are almost invariably non-pigmented, the spheroidal body is nearly always richly pigmented. The segmenting bodies of the estivo-autumnal parasite are found exclusively in the viscera, and especially in the spleen, marrow, and brain. These forms differ

Fig. 4.



Estivo-autumnal parasites.

from the tertian rosettes in being distinctly smaller in size, on account of the smaller size and lesser number of the spores. The number of the spores appears to vary from twelve to eighteen.

Beginning with the pigmented spheroidal body, a second developmental cycle, usually regarded as sterile, seems to occur in established cases of estivo-autumnal malaria. The end product of this cycle is the fully developed crescent, between which and the spheroidal body all transition stages may be readily followed in many cases. The spheroidal body becomes first ovoidal or elliptical, then elongated, and finally crescentic. The adult crescent is a very characteristic form. When deeply stained with eosin it usually shows a reddish stained outer membrane. Stretching across the concavity is a thin, apron-like membrane, which is probably the rem-

nant of the red cell. The body of the crescent stains unevenly, and is usually much lighter at its central portion, where a darkly staining point may sometimes be seen, and where there is an abundant collection of pigment. The pigment of all stages of the crescent is very coarse and distinctly golden-yellow in color. Pigmented mononuclear leucocytes are frequent and of very characteristic appearance in established cases of malaria. The pigment occurs in single grains or in peculiar clumps.

ANCIENT FULL-TERM ECTOPIC PREGNANCY.[1]

By J. WESLEY BOVEE, M.D.,
of Washington, D. C.

The rarity of old cases of full-term ectopic pregnancy, together with a few interesting matters met with recently in a case of this kind, has led the writer to briefly call your attention to the variety of conditions included under this general heading. Perhaps the best method of presenting the subject will be to recite the history of that case, which is as follows:

Mrs. J., white, thirty years old, residing at Wakefield, Westmoreland County, Virginia, a plantation historic for having been the birthplace of General George Washington, was sent to my service in Columbia Hospital for Women by Dr. William Washington, her family physician, in March, 1898.

During her girlhood she did not enjoy good health. Her menses began at the age of fourteen years, were irregular for the next few years occurring but two or three times annually, but later became quite regular for a few months, and then for a number of months at a time were absent. This irregular interruption of the flow for months has continued to the present time. Living in a malarial region she has suffered more or less from malarial poisoning all her life, and this with measles and other slight diseases, has kept her in bed a great deal. All during her premarital life she was very much annoyed with leucorrhea. She was married at eighteen, and three or four months later had an abortion, which was attributed by her physician to heavy lifting. Her health continued about the same, and twelve months later she was delivered of a female child after a short and easy labor. No physician was present. Previous to its birth her face, eyes, feet and genitals were swollen.

There was nothing of note in her condition until about December, 1888, when she began to have severe pain in her left inguinal region and left hip. A "knot" appeared in this region and gradually increased in size; a little later fetal movements were felt and she expected to be confined in August, 1889. "August 1, 1889," Dr. Washington wrote, "she was in labor, after having all the symptoms of pregnancy, and when I saw her August 15th, a diagnosis of extra-uterine pregnancy was made and the patient advised to call a surgeon." The pains continued about three months, after which period they gradually became less, but occurred with relapses sufficient to keep her in bed. Three years ago she gave birth to a live child, and during this pregnancy seemed to suffer no more than previously. The labor was short and much easier than the first, eight years before. During the following year the patient enjoyed better health than before, but at the end of that time had another relapse and "was just able to drag herself around." Her weakness increased and two months before being admitted to the hospital she was obliged to remain constantly in bed. Two weeks before admission she experienced great pain in the rectum and Dr. Washington removed therefrom the left parietal bone of the fetus which she brought to the hospital. She had been obliged to take quite large doses of morphin at regular intervals during several months and was clearly a victim to it. She was greatly emaciated, suffered constant pain, and was extremely sensitive to pressure in the left iliac region. An examination revealed the presence of a firmly fixed tumor in the left side of the abdomen, extending from the vagina to the spleen. A finger in the vagina elicited a sense of crepitation in the mass so easily felt in the left broad ligament, slightly in front, which was thought to be a fetal skull.

An operation was performed March 10, 1898. The vaginal route for removal was rejected unless an abdominal exploration determined it to be the preferable one. When the abdomen was opened the dense mass was found to be lying behind the peritoneum, and an attempt to reach it by an incision through the extraperitoneal structures in the flank was made and abandoned, as too much dissection seemed necessary and the liability to open the peritoneal cavity too great. An attempt to stitch the peritoneum covering the sac to the edges of the abdominal incision resulted in failure, and it was decided to pack gauze about the abdominal incision and all around the point in the sac wall elected for its opening. The sac was then incised, and from it after long, tedious efforts, the skeleton of a fetus, one or two bones at a time, was detached and removed with a considerable quantity of fecal matter. No other parts of a fetus were found, and no evidence whatever of a placenta was detected. The head was found near the spleen and the relation of the bones with the wall of the sac rendered great care necessary to prevent puncturing the peritoneum. The skin and peritoneum of the edges of the abdominal incision were united with running catgut suture and the edges of the sac wall were in turn stitched to the edges of the abdominal opening. The cavity was then irrigated and packed with iodoform gauze around a rubber drainage-tube. Two quarts of standard salt solution was run into the abdominal cavity to be absorbed. The opening (or openings) between the sac and bowel was not found or searched for, and as was expected, the bowel movements

[1] Read at the Annual Meeting of the Virginia State Medical Society, held at Virginia Beach, Va., Aug. 30, 31, and Sept. 1, 1898.

came through the opening of the sac for nearly two weeks, after which time it began to come through the anus and the fistula to close. April 1st there was scarcely any fecal matter coming through the opening but quite a little pus. April 10th she was gaining rapidly, taking on flesh and color, and walking about the ward free from pain, although she had had no form of opium since the operation. She left the hospital for her home in May in better health than during the previous eight or nine years.

Extra-uterine pregnancy was not well known until the publication, in 1836, of Dezeimeris' classification, and remained a very vague subject up to the appearance, in 1876, of the classical work of John S. Parry of Philadelphia. After these came Tait's house-cleaning work of the pathology of this condition. This form of pregnancy had been occasionally noted, however, for nine hundred years. Many writers refer to Albucasis[1] as being the first to clearly report a case of ectopic pregnancy. He was an Arabian physician, living in Spain, where, about the middle of the Eleventh Century, he saw parts of a fetus escaping through the abdominal wall of a woman by the process of suppuration. During the Sixteenth Century, Platerus,[12] Horstius,[8] Polinus,[18] and Primerose[14] reported cases fairly well authenticated. Those of Nufer[11] and Christopher Bain[3], both classical and overlooked by many historical writers on this subject, occurred about this time. It is probable that Jacob Nufer did the first abdominal section for extra-uterine pregnancy though his operation is considered as the classical first case of Cæsarean section on the living woman. The report of it appears in the collection of Casper Bauhin, and is recorded in Von Siebold's "History of Obstetrics"[16] as follows:

"According to the relation of Casper Bauhin, in his appendix to the Latin translation of Fr. Rousset's writings upon Cæsarian section, Jacob Nufer, a swine-spayer at Sigerhausen, in Switzerland, in the year 1500, delivered his own wife by opening the abdomen and the operation proved successful for both mother and child. The woman was pregnant for the first time and when labor came on and she had already suffered severely for several days, there had gradually assembled at her bedside thirteen midwives and several lithotomists. But all of them together were unable to relieve the poor woman of her child or to mitigate her suffering. Thereupon the husband of the woman proposed to resort to the last means of saving her and assured her that if she would take his advice, he hoped by the blessing of God, to bring the case to a successful issue. She gave her full consent and Nufer persisted further in having the permission of the magistrate to his attempt. This, after some reluctance, was eventually obtained. Nufer next asked those of the midwives who had sufficient nerve for it to assist him in the delivery of his wife, while the more timid ones were requested to leave the room. Eleven of them chose the latter course while two of them and all of the lithotomists remained to assist. The husband first besought the help of the Almighty, then closed the door, laid his wife upon a table and made an incision in her abdomen in the same way he was accustomed in the swine. He opened the abdomen so cleverly at the first incision that the child was safely extracted. When the eleven midwives outside the door heard the baby cry they desired admission, but this was refused until the baby was washed and the wound closed as in the swine. It healed rapidly. She was later confined four times and bore twins. The child delivered by the operation lived seventy-seven years."

Forty years later, according to Donatus, Bain's abdominal operation was deliberately done for the removal of a long-retained fetus. It is described as follows: "In April, 1540, at Castrum Pomponii, commonly called Pomponischi, in the Province of the Lords of Gonzaga, not far from the river Po, there lived a woman whose name was Lodovica, but from her great size termed "La Cavalla." She had been pregnant and the fetus had died in the uterus, while the soft parts had sloughed through the vulva and the bony portions had been retained within her. She recovered and again became pregnant followed by rapid loss of flesh and was reduced to a condition of great danger. Christopher Bain, a traveling surgeon, happened by and offered to attempt to restore her for ten golden pieces if successful and her body if she died. She and her relatives were very poor and most of the money was raised by their good neighbors. The woman was tied up; he slowly cut through the abdominal wall including the peritoneum and at last opened the uterus and extracted the skeleton of a male child; he washed out the uterus with some warm wine and aromatics and after cauterizing the edges of the wound closed it with a suture. She recovered and in a short time had other children born in good condition. Later she had four in all. Witnesses: Dominus John Baptist Zorzonus and Alexander Begher, Dominus Frederick de Filini and Dominus Leonellus Zorzonus, and Antonius Maiochus or Mazzuchinus, and several others present at the whole operation."

This operation was probably for an ectopic gestation and was done fifty-four years before that of Primerose. About this time Platerus did his operation successfully (1594). In 1604, according to Webster,[19] the first case of tubal pregnancy was re-

ported by Riolanus, the younger, and the same author regards the first case of ovarian pregnancy reported to be that of Mercerus, in 1614. But of abdominal pregnancy the first good account was by Josephi,[9] in 1784, and the first clear description of interstitial pregnancy was by Dionis,[6] in 1718. To Madame Lefort belongs the credit of having first reported clearly, in the Eighteenth Century, a case of developed ovum between the layers of the broad ligament, a condition that in 1836 was called by Dezeimeris "Subperitoneo-pelvic" pregnancy. Lawson Tait's investigations led to the determination that practically all cases of extra-uterine pregnancy are originally tubal, becoming other varieties, often by escaping from the tube. His views on this subject are generally accepted by the profession. It is interesting to note that most early writers considered that the fetus had escaped from the uterus, and gave histories of injuries at some date during the pregnancy that had caused such extrusion. Altogether the study of these early cases is very enchanting.

The longest period I have found mentioned during which a fetus had been retained in the abdomen of its mother was fifty-seven years (Nebel's[10]). Sappey[16] reported 1 of fifty-six years, and I found 9 others of more than fifty years; 6 between forty and fifty years; 10 between thirty and forty years, and 43 between eight and thirty years, besides a considerable number in which autopsies on aged women revealed the presence of dead fetuses in various stages of decomposition, and without histories of pregnancies.

The condition of the fetus in ancient ectopic pregnancy is variable, being apparently but slightly dependent upon the length of time it had existed. Bayle[3] removed post-mortem from a woman's belly a fetus in good state of preservation that had been there twenty-six years, and Watkins[18] 1 forty-four years old that was loose in the abdomen and perfectly well-developed and preserved. *Per contra* many cases are found in which trouble has been caused by putrefaction, septic infection, sloughing into hollow viscera, or other depressing condition, within a very short time after the death of the fetus. It would seem that the duration of retention of an extra-uterine fetus of advanced development depends largely upon whether the conception product becomes infected. The limit of time during which these fetal cysts may remain in the abdomen unmolested has not been determined, inasmuch as in a number of the very oldest cases death was due to some entirely irrelevant cause. In about 76 per cent. of cases (Charpentier[5]) infection occurs and Nature attempts to eliminate the foreign material and is oftentimes successful, though in a large majority of them, if unaided by surgery, the women die of exhaustion as a result of pain, long profuse discharges, or sepsis. In the remainder, about 20 per cent., the fetus remains either in a fair state of preservation or is changed by fatty degeneration, absorption of the soft parts, calcification of the sac wall, or other metamorphosis. A true lithopedion of the fetus does not form. Elimination when attempted is, in about half the cases, into some portion of the bowel, nearly as often through the abdominal wall at some point, far less frequently through the bladder or vagina, and in one case[20] through the perineum.

Various authorities have insisted that nearly all cases of full-term ectopic gestation are intraperitoneal. This is not readily reconciled with the preponderance of evidence to prove that the absorption of a young ovum placed in the peritoneal cavity progresses rapidly. Taylor[17] and Webster agree that abdominal intraperitoneal gestation is uniformly fatal (unless removed by abdominal section), primarily by hemorrhage, secondarily by suppuration of the sac, and peritonitis. Of course the amount of hemorrhage may be so slight as to cause no alarm and is usually least when rupture is near the fimbriæ. Again, the fetus may escape in its unruptured membranes into the peritoneal cavity, the placenta preserving its attachment to the inner surface of the tube. Webster, Taylor, and others have recently published views directly antagonistic to this belief, and I believe that while it is possible to retain a fetus sufficiently long in the Fallopian tube for its arrival at such a stage of development that when suddenly expelled into the peritoneal cavity it will resist absorption, and that intraperitoneal pregnancy may occur without passing through the broad ligament, practically all full-term ectopic gestations are, or have been, broad-ligament pregnancies. Either the pregnancy develops and remains extraperitoneal, bulging either the anterior or the posterior fold of the broad ligament, or finally ruptures through the peritoneum into its cavity. The case herein reported, and one I previously recorded[4] were unquestionably extraperitoneal. Dunning's interesting case[7] was of this variety, and many of those reported during the past few centuries were clearly proven to be of this type. It is probable those old cases that opened into the bladder, vagina, or perineum, or into the bowel, as did the one herein detailed, were of this variety, and even some of those opening through the lower part of the abdominal wall may have dissected up the anterior layer of the peritoneum and escaped without ever having invaded the peritoneal cavity.

Another interesting feature of the case herein re-

ported is that while in possession of the old ectopic gestation the woman again became pregnant and was delivered of a living child after a very easy labor. This interesting condition has occurred in at least quite a large percentage of the cases I have studied and, even in a few instances, two different ectopic pregnancies have been found at the operation or autopsy. These were usually of different stages of development, but either of the same date and one becoming blighted first or altogether different as to age.

Parry and others of the early writers on the subject of full-term ectopic pregnancy have been opposed to surgical assistance except when the life of the woman was clearly in immediate danger. But that was before surgical invasion of the peritoneal cavity was so safe as it is now, and the views expressed have been gradually tending toward surgical relief as the routine treatment for this condition. The principal cause of death in abdominal section for these advanced cases is sepsis. It would seem that if the large majority are extraperitoneal, many of them would not require celiotomy. However, if a transperitoneal operation be necessary, then treatment of the sac by stitching it to the abdominal wall before opening it, or when not possible, afterward, would be the most approved plan of procedure when the sac cannot be enucleated. When much denudation of tissue in the pelvis results from cystectomy then drainage through the vaginal roof will be advisable. Although the operation may be performed in a thoroughly aseptic manner, if in these greatly weakened women a space is left in which accumulation of fluids may exude, one must expect its infection before its absorption occurs, and a considerable loss of life to result.

A SINGLE TEST OF THE VIRULENCY OF SPUTUM KEPT MANY MONTHS.[1]

BY IRWIN H. HANCE, M.D.,
OF LAKEWOOD, N. J.

THE virulence of tubercle bacilli, as demonstrated by the clinical pictures of pulmonary tuberculosis and the experimental results on animals, presents a very wide range for our consideration; the resistance of these germs against disinfectants is also known to be great, and, consequently, one may expect them to retain their power of infection for many months. Stone,[2] in 1891, reports an experiment in which tubercle bacilli retained their form and virulence for three years. The writer undertook a similar experiment, and with a result so different that he deems it worthy of being reported to this Society.

On February 18, 1896, six guinea-pigs were inoculated with sputum which was secured from an old chronic case of pulmonary tuberculosis with large cavities. Eight weeks later all the animals were killed. General tuberculosis of the glands and of the abdominal and thoracic organs was found in each pig. Large-mouthed bottles half full of sputum stopped with big corks were put away in a pasteboard box on the top shelf of a closet until July, 1897, seventeen months later. The contents when examined were still of fluid consistency, about half the original quantity, of dark-brown color, very little odor, and with considerable deposit. After thorough mixing of this sediment, 1½ c.c. was inoculated into the peritoneum of one and under the skin of a second guinea-pig. The former died in forty-eight hours from some septic poison; the latter lived thirty days, when it was killed. At the autopsy no glandular enlargement and no evidences of tuberculosis were found.

On the same day 2 c.c. of the sediment was mixed with 2 c.c. of sterile water and centrifuged for ten minutes. I thought thereby to obtain the bodies of the tubercle bacilli without the toxin apparently present in the fluid. To this deposit in the tube, after decanting the supernatant fluid, 2 c. c. of sterile water was again added, and equal parts of this was injected into the groins of two guinea-pigs. Twenty-eight days later both pigs were killed, and the autopsy gave a negative result. It should be noted that neither one of the pigs in

[1] Read at the Fifteenth Annual Meeting of the American Climatological Association.

[2] Stone, *Amer. Jour. of the Med. Sciences*, March, 1891.

the second experiment was at all sick after the inoculations; also, that the microscopic examination of the centrifuged sediment did not show any clearly outlined bodies of the tubercle bacilli, but fragmentary masses which retained the coloring matter, and were pronounced to be disintegrated tubercle bacilli by two other examiners in addition to the writer.

Having secured a negative result with this second experiment, one is justified in concluding that the tubercle bacilli in this case were no longer viable, and the following queries suggest themselves: Does sputum which remains in a liquid state for a long time develop toxins which are inimical to the life of tubercle bacilli? Would the result have been different had the sputum been more virulent in its character and taken from a case of acute active tuberculosis? If sputum dries more rapidly, does it retain its virulency longer? These can be answered only by further experimental work; and if the third query should be proven in the affirmative, it will be in accord with other experiments made with dust from rooms long since occupied by tubercular patients, and furnish an added reason for disinfecting and cleaning the habitations of such persons.

CLINICAL MEMORANDUM.

SOME ODD MALARIAL MANIFESTATIONS.

By R. A. GOODNER, M.D.,
OF NASHVILLE, ILLINOIS;
FORMERLY PHYSICIAN TO THE ILLINOIS SOUTHERN HOSPITAL FOR THE INSANE.

THE atypical manifestations of malaria may present symptoms indicative of ill-defined perversion of the general health, or they may indicate perverse or defective function upon the part of some organ, simulating local disease of the same, and may or may not be accompanied by other symptoms, oftener due to and easier interpreted as malarial. These many different symptoms of malaria upon the part of organs apparently unrelated, either from an anatomic or physiologic standpoint, showing so little relationship to the common and expected types of malaria, are to my mind best explained by a defective or perverse innervation of function of the parts affected.

That the extraordinarily protean character of malaria is not better understood, odd cases not more readily diagnosed, especially by recent graduates in medicine, is to a large extent due to insufficient attention given this phase of the subject by teachers and authors. It may be that one reason for this is that our teachers and text-book writers mostly live in large cities where malaria is much less prevalent, and perhaps less protean, too, than in the country districts.

An examination of the blood for the plasmodium malariæ is an important, scientific, and advanced means of diagnosis, but obviously not always practical at the bedside, even if the physician has the requisite skill and inclination to make a microscopic examination; and if there is a scarcity of the organisms in the peripheral blood, as is frequently the case for the first few days, it would be a tardy diagnosis if one were to depend wholly upon this means. Again, if one is not suspecting and searching for a malarial origin in conditions which may be atypically malarial the necessity of a blood examination will not likely be appreciated. Considering how widespread and prevalent malaria is, what a large percentage of the average country practitioner's cases are malarial, at least in many parts of this country, I wonder that more attention is not given the subject. To elucidate what I have written I append histories of some of the cases I have seen, with one exception during the past year:

CASE I.—Female, housewife, aged twenty years; previous health good. Became suddenly ill, with all the usual symptoms of catarrhal dysentery presenting, and it was so diagnosed by the attending physician. After one week of treatment by the usual remedies, she being unimproved, I was called. I found her very weak, having very frequent stools, accompanied by tenesmus and composed principally of blood and mucus. Temperature 102° F.; pulse 102. No history of chill or any prominent remissions or an intermission of temperature. It seemed to be a typical case of catarrhal dysentery. Bearing in mind the possibility of malarial infection I questioned closely and the only evidence I was able to elicit which indicated malaria was a periodic exacerbation of the prevailing symptoms. This, together with the fact that malaria was prevalent in the neighborhood, and that I had previously seen somewhat similar cases undoubtedly due to malaria, led me to strongly suspect a malarial origin. I gave her quinin, with a resulting rapid disappearance of all symptoms.

CASE II.—Male, teacher, aged twenty-five years. Had a severe diarrhea accompanied by pain. Temperature and pulse normal. Slight nausea present but no vomiting. No history of dietary error; similar attack two days previously, same hour, lasted a few hours and completely subsided; during interval between attacks felt fairly well. This patient presented the usual symptoms of an ordinary diarrhea, the same being at the time more or less prevalent, and the physician who treated him for the first attack made this diagnosis and treated him accordingly. The element of periodicity manifest in the second attack, the fact that preceding the first attack there had been an initial period of malaise and ill-health, the most prominent symptom of which was "a tired, aching feeling in the bones, arms, and legs," and the absence of any symptoms or history of dietary or other cause led me to diagnose a malarial origin. Quinin relieved the patient and he suffered no subsequent return, as he would have done without an antimalarial agent.

CASE III.—Male, aged fifteen months; weaned; diet principally cow's milk. Severe diarrhea; had lasted three weeks. Temperature 102° F.; pulse 150. This patient, from a near-by city, was sent to the country upon the recommendation of his attending physician with the hope that the change would prove beneficial. The diagnosis of subacute milk infection had been made. By

close inquiry I learned that during the first few days of the fever the mother had noticed for several days at about the same hour, *cutis anserina*, and from this I inferred the temperature had perhaps intermitted during the first few days, but from the statement of the mother there had not been a subsequent intermission or prominent remission. After the first few days the patient presented similar symptoms as those present in the disease diagnosed and led the attending physician into error. Cases similar to the above are not uncommon, both as to symptoms and diagnosis. The only clue to malaria was shown in the first few days, and in this case, as well as in many others, the physician will not obtain a satisfactory history without much cross-questioning, always bearing in mind the possibility of malarial infection. This patient's fever, diarrhea, and accompanying symptoms disappeared under the administration of quinin in twenty-four hours.

CASE IV.—Female, aged thirty-eight years; housewife. Previous health good. Presented usual symptoms, objectively and subjectively, of ulcerative stomatitis. She was nursing her baby at the time, and told me she had "a nursing sore mouth." Concurring in her diagnosis I gave the usual treatment for a week or two, but without good results. Visiting me subsequently I questioned her more closely and learned that previous to her first visit she had had for several days vague and slight periodic manifestations of fever, the same having become more prominent since then. Recognizing a malarial cause or complication I gave her quinin, with the result that she speedily recovered. One year later she wrote me she was having the same trouble with her mouth, had tried several physicians without relief, and for me to send her some more of the same medicine, etc. I did so and she quickly recovered. The following fall she had a repetition of the same trouble and quinin again relieved her.

CASE V.—Female, servant, aged twenty years. Temperature and pulse normal; no history or symptoms of the ingestion of any food or drug likely to produce symptoms present. She presented the typical lesions of urticaria. For a short time she had complained of feeling tired, of aching in her bones, legs and arms, but otherwise did not have any indications of malaria. Quinin gave her complete relief in one day. This therapeutic test, coupled with the fact that I have seen at least twenty similar cases during the past year, most of them affording common and unmistakable evidences of malaria, each responding readily to quinin, in some instances after the failure of other treatment, absence of symptoms upon the part of the stomach, no history of the ingestion of any drug that might produce the disease, leads me to class this case as malarial, and my experience teaches me that in a malarious district nineteen cases out of twenty of urticaria are due to malarial infection.

CASE VI.—Female, housewife, aged fifty years; consulted me last September for a severe acute conjunctivitis, accompanied by an intense and constant supra-orbital pain. No temperature. The usual treatment not affording relief, the supra-orbital pain becoming subsequently periodically exacerbated, led me to try quinin in addition to the local treatment she was receiving and she speedily improved.

CASE VII.—Male, laborer, aged thirty-five years. Previous health good; no temperature; pulse normal. Consulted me for several small ulcers of two-months' duration upon the outer side of the middle third of his left leg. No history or evidences of syphilis or any diathetic condition. No causes or symptoms locally that would account for the ulcers. Previous treatment without results. Continuing the local treatment and giving quinin caused a marked and rapid recovery.

CASE VIII.—Male, farmer, aged thirty years. Previous health good; no family or personal history of rheumatism or neuralgia. Consulted me for a painful but not swollen knee. Had been under treatment for several weeks without relief. I learned there was a periodicity to the painful exacerbations, otherwise the history was negative as to malarial indications. Quinin promptly relieved and cured him.

CASE IX.—Male, coachman, aged twenty years. Temperature and pulse normal. Personal and family history excellent. Presented a typical case of Bell's palsy, of three-day's duration. There were no premonitory indications whatever, neither was there evidence or history to show any trauma or exposure to cold. There were not any ascertainable malarial symptoms previous to the attack of paralysis, but subsequently he had been having fever, so he said, the same coming on about 3 P.M. and being more pronounced the last day as compared to the two previous ones. Knowing that cases of paralysis had been reported as of malarial origin, I gave quinin, with the result that he was practically well in three days.

CASE X.—Male, school-boy, aged sixteen years. Temperature and pulse normal. Of previous good health and of good parentage. Consulted me for a paralysis of the extensor muscles of the right hand of two-weeks' duration. Previous treatment had been without results. There was no evidence or history of any traumatic cause. I treated him without benefit for about two weeks, then he developed a typical case of intermittent fever, and by further questioning I learned for the first time that previous to the paralysis he had had intermittent fever. Putting him on quinin he was greatly improved in three days and at the end of a week was well.

I am aware that some writers are skeptical as to the malarial origin claimed for some of the oddly manifested cases that have heretofore been reported, but in the above cases, with the exception of Case IV., a microscopic blood examination was made and, in each instance, some one or the other varieties of the malarial parasite was found, confirming the suspicion or diagnosis of a malarial origin. In several of the cases it was only after the examination of several specimens that the parasite was found. Some authorities have explained these oddly manifested cases as being complications of malaria and not directly due to malarial infection. If such is the case why do the complications respond so surely and readily to quinin, the complications in question being diseases that usually with the best of treatment require a much longer time to cure?

SPECIAL ARTICLE.

THE GARRISONING OF OUR TROPICAL ISLANDS.[1]

BY SENECA EGBERT, M.D.,
OF PHILADELPHIA;
PROFESSOR OF HYGIENE AND DEAN OF THE FACULTY IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

AT the present moment there is probably no subject of more general interest than that which concerns the health and welfare of those who are to form our army of occupation in our newly acquired territories.

We have just had a sad and bitter experience. Here at home, within easy reach of everything necessary to health and comfort that science could suggest or money buy, widely separated camps have been devastated by most serious epidemics; while in Cuba, for which our troops are now embarking, an army of 18,000 men of magnificent courage and heroic action, has been utterly incapacitated by sickness, and forced to leave to others the field so gallantly won. It is not our purpose to criticise or to comment upon what is past; the readers of the MEDICAL NEWS have already formed an opinion, be it just or unjust, and we need not attempt to strengthen or to change it.

Now that our flag floats over Cuba, Porto Rico, Hawaii, and the Philippines all realize that large numbers of our soldiers must be sent to garrison these tropical and semitropical countries, and that their term of occupation must be an indefinite and perhaps a long one. The question that confronts us is: Must we look forward to the inevitable incapacitation of this large force by disease and death, or is it possible, with our present sanitary and scientific knowledge, for this army to carry on its important work in comparative safety and immunity?

Thanks to natural conditions and Spanish misgovernment and neglect, these countries are the endemic home of typhoid fever, of yellow fever, and of other deadly miasmatic infections. The streets and harbors of Havana and other cities reek with the filth of four centuries, and the labor of cleansing these and making them sanitarily safe will be more truly herculean than the purification of the Augean stables.

What Great Britain has been able to do in the way of reducing and banishing pestilence in her colonies of the Far East, and more especially in Jamaica, so similarly situated, and at one time as unhealthy as these new possessions of ours in the Carribean Sea, is a matter of history. England's experience and success certainly makes it more easy for us. Never have the laws of hygiene and sanitation been so well understood as now. Great strides are being made in improving the sanitary condition of all our large cities, and this same advance can be secured with more marked effect in the places to which reference has been made. The strict observance of a comparatively few simple but important rules and principles will almost certainly protect and preserve the health and lives of the great majority of our army of occupation during its sojourn in these foreign climes.

It is with the idea of formulating and outlining a systematic method of procedure looking to the sanitary care of all engaged that we have ventured to offer the following propositions. We must of necessity leave much of the detail to be filled in by others, but we hope to be able to present the main points in such a way as will awaken and unify the interests of our profession in the main subject. We shall consider later the climate and natural conditions of these tropical or semitropical countries, and inquire as to the extent to which they are responsible for the prevalent maladies.

As far as possible, every preparation should be made for the care and domiciling of our soldiers in these foreign lands even before their departure from home ports. In other words, their camps should be carefully selected, their barracks or quarters should be arranged for, and, whenever feasible, constructed of new materials and in accordance with the dictates of modern sanitation. An adequate water-supply should be provided, and every provision made for its thorough sterilization. Food, medicines, and supplies of all kinds for any emergency should be sent in abundance and in advance, that they may be on hand when the men arrive, and, in fine, everything should be done that the intelligence and unlimited resources of this country may justify.

In the meanwhile, we would offer the thought that the time between now and the departure of the several bodies of troops can be spent in no better way than in giving the men didactic and practical instruction in hygiene and sanitation. This may seem pedantic and pragmatical to some. But it must be remembered that our soldiers are intelligent and, for the most part, fairly well educated, and that, warned by the bitter experience of the past summer, they will be the more ready to observe and obey the orders which their reason commends. Many of them are members of our volunteer service, and many are more or less closely related to some of us. The writer's hospital experience with not a few of them from different States has convinced him that they represent at least something more than the average intelligence of the country. Why not, then, have definite instruction given by officers of the army medical staff, or even by competent persons outside of the military service, both by means of lectures and by practical experiments and demonstrations? Let it be explained to them in ways that they will realize and remember that most of the dangers from disease to which they will be exposed must come to them either in the air they breathe, the water they drink, or the food they eat; that the risks from the latter two can be avoided by exercising moderate prudence and care, and eliminated, with regard to the former, by good ventilation. Make it plain to them that the soil of these countries is the habitat of and is infected with miasmatic organisms, and that to sleep on the ground is to invite attacks of malaria and kindred fevers; and grind it into the very fiber of their mental and physical economy by making them live now as they must live then.

One soldier, to the writer's knowledge, went through

[1] The first of a series of articles relating to the preservation of the health of our army of occupation.

the Santiago campaign with few, if any symptoms of the almost universal fevers that wrecked that intrepid army corps. But, being previously informed, he took the precaution to boil every drop of water that he drank. How many more would have escaped as he did, and how many lives would have been saved, had all his comrades had the same foresight and knowledge, or had they been compelled to observe the same precaution? What better evidence of the advantages of hygienic forethought and sanitary care could we have than that afforded by the marines who were the first to land at Guantanamo, and for ten weeks were exposed to the same conditions as was the larger army within a few miles of them? How was it that their sick-rate did not exceed 2½ per cent. at any time when the larger force had 75 per cent. unfit for duty within four weeks, if it is not that they had proper food and drink, proper clothing, and proper attention? Do not these facts warrant the attempt to give every enlisted man better information in regard to sanitary matters?

Certainly some of those to which such instruction might be given would appreciate it, would try to utilize it, and would profit by it. By their example and evidence, they would also benefit their comrades. The possession of the "first-aid packets" of aseptic dressings, which were supplied to the troops, and the general knowledge of how to use them, certainly saved many lives in the late campaign. Now we must go one step further and teach the men how to guard against disease as well as against the injuries caused by the bullets of the enemy.

The importance of this instruction cannot be overestimated. It is a well-known fact that the Medical Department of the Spanish Army in Cuba was well officered and well administered. The medical records of their military hospitals are models of accuracy and bear evidence on their face of the competency and efficiency not only of the surgeons in charge, but also of their subordinates. The source of their appalling mortality can be traced to the fact that the Spanish soldier, officer and private, was young, reckless, and ignorant. Hygeia, to him, was an unknown goddess and sanitation a myth. Medical instructions and orders were regarded with indifference, and the inevitable results followed. The self-same conditions prevailed throughout our volunteer camps and were attended with similar results. The official orders of instruction issued by the Surgeon-General of the Army were model documents, clear, exhaustive, complete. But neither the privates, the junior officers, nor, it is to be feared, the commanding officers themselves, knew enough to take them seriously and enforce them.

It will undoubtedly be possible in the near future to garrison both Cuba and Porto Rico with American troops with comparatively small risk to the health and lives of those concerned. But it is also more than probable that such safety cannot, at the present juncture, be ensured, and that the conditions must be greatly altered before such a consummation may be attained. The report of the Sanitary Inspector of the United States Marine Hospital Service for Havana for the various weeks, beginning October 1st, states that while yellow fever does not exist to the same extent as it has existed during the past two years, the reason being that during the past eight or ten months but little material has been present on which the fever could feed, on the other hand, malarial fevers in fatal form exist to a marked extent, and enteric fever and enteritis furnish more than one-fifth of the total deaths. He also adds that "the city is even dirtier than ever, if such a thing could be possible."

Admitting that the yellow-fever season in Cuba is almost, if not quite, over at the present time, it is quite possible, indeed, more than probable, that large numbers of men, no more immune than are the majority of our troops, will develop the disease when exposed to the new and peculiar climatic conditions and environments. The lamented death of Colonel Waring also makes us realize that even the highest scientific ability and sanitary knowledge will not insure the medical improvements necessary without some costly sacrifices.

If the troops are to be sent to the cities, can a place where the annual death-rate, though even for a limited time only, is practically *seven* times that of New York or Philadelphia, be in its present condition a proper location for a garrison of American troops? Of course, Havana is not the whole of Cuba nor San Juan of Porto Rico, but it is in or near the large cities that some of the garrisons must first be located to maintain order and establish a permanent government. In confirmation of this, the orders of the Adjutant-General of November 4th, assigning the various corps and divisions to their respective stations, ordered them to hold themselves in readiness to proceed to Cuba, presumably upon short notice. Doubtless, there is full need for this early despatch of many soldiers to Cuba, especially to maintain order when the Spanish troops have been withdrawn.

The Secretary of War has recommended that the Cuban insurgents, in such numbers as may be secured, be enlisted in the United States service, and be officered by Americans. The idea is certainly a good one, and unless there are grave objections to it, which cannot now be foreseen, it should be tried. Many who would thus enter the service would doubtless eventually desire to remain therein, would the quicker learn the full meaning of the principles of our government, and continually tend to lessen the number of our own men needed on the island. England has maintained native West-Indian troops since 1795, and their service has always been, we believe, most satisfactory.

Though the duty of the country is plain before it, and it may not hesitate in its doing, it is also certain that, no matter how much has been gained by this war for humanitarian ends, humanity will not be patient with any management that unnecessarily sacrifices or even jeopardizes the lives or the health of the troops. When the transportation of the various detachments does occur, they may fairly expect to find awaiting them upon their arrival every reasonable preparation and accommodation that the greatest foresight and widest experience can suggest. There can and will be no condoning of any failure to make these provisions and preparations. Now that every one knows from recent experience just what the

dangers are, and that they are real and unexaggerated, the utmost care in the avoidance of them must be taken.

One phase of this great problem relates to the selection of the men who are to form the armies of occupation. The MEDICAL NEWS has already quoted General Lawton as saying that "the American troops are very discontented in Cuba and want to return home. In my mind, the time will never come when the American soldier will serve in Cuba contentedly." Practically the same story comes in the reports from far-off Manila, and, if we mistake not, from Porto Rico. Nostalgia or homesickness is something more than a matter of sentiment, and beyond the reach of the ordinary materia medica.

Consequently, since the going of the soldier to these countries is unavoidable, it becomes the more necessary that everything should be done to make his service and stay reasonably agreeable, and to lessen his discontent. It shall be our endeavor to discover and present in future articles how this may best be accomplished. The American soldier will be expected to undergo hardships when necessary, for that is part of his business and contract, and he would not be an American soldier if he did not. But he may also justly expect in return that the service shall not be needlessly disagreeable or disheartening. It will be remembered that when many of the volunteer regiments entered the Government service, the enlistment of married men and those who had families dependent upon them was discouraged. The thought suggests itself here, and will be more fully developed later, that it may be wise to eventually reverse this rule, and for the purpose of garrison duty to select married men as far as possible, and to send their families with them or to them as soon as provision for the latter can be made. This would cost something, but the results would justify the expenditure in that for many the greatest cause for discontent would be removed. Moreover, this would be a controlling influence in the prevention and regulation of venereal diseases of which we will have more to say hereafter.

MEDICAL PROGRESS.

Cyclic Vomiting.—WHITNEY (*Arc. Pediatrics*, November, 1898) describes a case of cyclic vomiting occurring in a boy eight and one-half years old. There were altogether six attacks, at intervals of almost exactly three months, without any ascertainable cause. Similar cases have been reported by other writers, some of whom have considered that the attacks were due to a uric-acid diathesis, and have treated the patients by salicylates or by some of the lithia waters. The symptoms have been thus described: A child, possibly delicate, but often in previously perfect health, after a prodromal period of twelve to twenty-four hours, is suddenly seized with vomiting. During the prodromal period the symptoms, which are not very pronounced, consist in lassitude, coated tongue, offensive breath, rings about the eyes, loss of appetite, and sometimes a sense of discomfort or distress in the epigastrium. The vomiting is of sudden onset, and often peculiarly severe and uncontrollable. It is excited by the slightest ingestion of food or drink, or it may be independent of either. At first, whatever food may be in the stomach is expelled, and afterward the vomitus consists of a moderate amount of strongly acid-watery mucus, very often streaked with blood. The latter is especially apt to follow the violent and painful retching which is usually present. This vomiting continues at longer or shorter intervals for from twelve hours to four or five days. There is usually a rise of temperature of two or three degrees at the outset, and a slightly lower fever continues until the cessation of the vomiting. Meanwhile, the general condition is often markedly affected, and there is usually a degree of prostration which seems out of proportion to the local manifestations. The abdomen is almost invariably retracted. With the abrupt cessation of the vomiting there is usually a rapid return of appetite and of the normal digestive processes.

The gastric crises occur at intervals varying from six weeks to six months. In any particular case the interval is likely to be always the same, and when the appointed time has elapsed the paroxysm is apt to come on in spite of the utmost care in the avoidance of unwholesome food and psychic disturbances. Indiscretion in these matters may bring on an attack at any time, although the child often enjoys good health in the interval. The real treatment is to strengthen the constitution by an active, out-of-door life.

Hot Air as a Hemostatic.—SCHNEIDER (*Beit. z. klin. Chirurg.*, vol. xxi, p. 805) finds that the ideal hemostatic for parenchymatous organs is one which will produce a thin crust all over the bleeding surface, closely resembling a normal blood-clot. The crusts produced by the point of a thermocautery are apt to stick to the hot iron and tear away from the organ when the point is withdrawn. Chemicals cause thrombosis. Compression with gauze is only occasionally satisfactory. He next tried steam, which had been highly commended by Snegirew. The apparatus was simple, and the results would have been good had it been possible to keep the steam at a high temperature at the point of exit. Unfortunately, he was unable to do this even with a slight pressure in the kettle, and if higher pressure was used the steam and hot water blew holes in the tissues. The surrounding parts had to be kept cool by gauze wet with cold salt solution, and there was considerable danger of producing shock. Finally, it failed entirely to control hemorrhage in divided muscles. He found hot air to work more satisfactorily. The apparatus for this was simple. A Bunsen-burner heated a coil of metal pipe, through which air was blown. It was not possible to have the pipe of exit from the heated coil to the wound more than a few inches long, else the air lost its heat so much as to be ineffectual. When it was working well, and air was escaping at 170° to 200° C. (338° to 392° F.), the current was directed upon the bleeding surface spirally, from the center to the circumference, and rapidly produced a light, tough crust, which could be washed without danger of recurrence of the hemorrhage. No shock accompanied this treatment, and it was proved by a thermometer placed one-fourth of an

inch under the bleeding surface that the temperature at that depth did not rise above 41° C. (106° F.) while the crust was forming, so there can be no question of deep injury of the tissues. The swelling of the organ and the tissues necessary for complete healing was less than when steam was employed. Thus far the method seems to promise much. There are still technical difficulties to be overcome, so that the lamp may be removed to a greater distance from the patient, say from eighteen to twenty-four inches. With this apparatus it was possible to keep up the heat at only half that distance.

Surgery of the Seminal Vesicles.—GUELLIOT (*Centralbl. f. Krank. Harn-und Sexual-Organe*, September, 1898) gives as indication for operative attacks upon the seminal vesicles, the occurrence of inflammation, stone, cancer, or tuberculosis. Old, inflamed vesicles with sclerosis of the surrounding tissues should not be extirpated. If, however, suppuration is present, and the pus, instead of flowing from the duct collects and threatens to break through into the peritoneum or into the perivesicular tissues the abscess should be opened from the perineum. Stones and cysts are not common. When present they should be removed through the perineum. Primary carcinoma of the seminal vesicles has never been operated upon as far as known. Tuberculosis, on the other hand, is the commonest cause of operation. The operative technic is as follows:

1. Lithotomy position with a catheter in the urethra.
2. Incision, concave backward, from the right ischiatic tuberosity to the left.
3. Separation of the urethra from the rectum.
4. Exposure of the levator ani and division of the same upon affected side.
5. Lifting of the anus with hooks and a speculum.
6. The prostate is drawn upward with forceps.
7. Blunt dissection of the prostate and seminal vesicles from the anterior wall of the rectum.
8. Removal of the affected seminal vesicle bit by bit.
9. Control of hemorrhage; suture of the deeper part of the wound; iodoform-gauze packing.

An Investigation of Stitch Abscesses.—TROLLER (*Beit. zur. klin. Chir.*, vol. 22, p. 441) has made a number of experiments in order to determine the cause of stitch abscesses, and the best means of avoiding them. He found that washing the skin with water sterilized it in about one-fifth of the cases; a single scrubbing with a disinfectant sterilized it in something more than one-fourth of the cases, while repeated scrubbings with disinfectants sterilized it in a little over one-half of the cases. In order to test the sterility of the sutures, he employed three kinds —aluminum-bronze wire, silk, and catgut. After a day or more the sutures were removed and tested bacteriologically. Separate tests were made for the portion of the suture embedded in the skin, and for that portion which was outside of the skin. Of eighty-four sutures which were examined in this manner, forty contained germs in their subcutaneous portion, as well as in their outer portion, and twenty-one others contained germs in the outer portion alone. That is to say, that seventy-three per cent. of the sutures contained germs in some portion. As was to have been expected, the results were better when the skin had been repeatedly scrubbed with disinfectants than when only a single cleansing had been carried out. Furthermore, the results with aluminum-bronze were far better than with silk or catgut, nearly three times better than silk, and more than three times better than catgut. The superiority of the wire was due apparently to its impermeability and smoothness. Tests were, therefore, made with silkworm-gut and with a silk made impermeable by gutta-percha. The results with these materials, while better than those obtained with silk and gut, were still inferior to those obtained with wire. Troller was, therefore, of the opinion that the wire possessed an antiseptic action, a view which has been held by other investigators. The bacterium usually found was the white staphylococcus, less often the streptococcus or some bacillus, rarely the yellow staphylococcus. The great majority of germs seemed to come from the skin itself, being either carried in from the surface by the eye of the needle, or following down the track of the suture afterward. In more than one-half of the instances in which the subcutaneous part of the suture contained germs, a visible stitch infection resulted. This was especially true of the catgut and silk sutures.

Albuminuria and Casts Due to Constipation.—KOBLER (*Wien. med. Blatter*, September 1, 1898) speaks of the albuminuria which occurs in connection with cholera. While investigating a case of chronic diarrhea in order to see if the casts were present under those conditions as well as in cholera, he observed that in the periods of constipation which alternated with the diarrhea, the albumin and casts were much increased. Later, he examined a number of patients suffering from some intestinal affection marked by obstipation, and in a number of instances he found that albumin and casts appeared during periods of constipation, and disappeared or became much less when the constipation was relieved. All of these patients suffered considerable pain, and Kobler is inclined to think that there was some causal relation between the two, especially as the pain increased and diminished at the same time as the albumin and casts.

THERAPEUTIC NOTES.

Properties of Podophyllin.—MACKENZIE and DIXON (*Edin. Med. Jour.*, November, 1898) have conducted an investigation into the powers of podophyllin, and find that the active principles contained in the crude resin are two substances, (*a*) crystalline podophyllotoxin, (*b*) podophylloresin, both of which act as excellent laxatives in small doses, without secondary constipation or other objectionable symptoms. Although both these substances act very similarly on the alimentary tract, it is only the podophylloresin which exerts a true cholagogue effect, which shows itself rather by a large increase of the solids secreted than by an increased quantity. Both exert their specific activity when injected hypodermically in alcoholic solution, but in man so much irritation is produced as to forbid their employment in this manner.

The physician should know whether he is prescribing the Indian or the American product, as the former is more than twice as powerful as the latter. The cholagogue effect of podophyllin has been estimated to be greater than that of any known substance.

Treatment of Erysipelas. — WINTER (*Maryland Med. Jour.*, September 10, 1898) says that so-called idiopathic erysipelas is almost always traumatic in character, usually having its origin in some excoriation about the nose or face. Such an attack is usually preceded by sore throat, thus indicating that the germs may find their entrance in this situation. The first treatment should be to induce free action of the bowels, kidneys, and skin. Calomel or some other mercurial purgative, or compound jalap powder should be given and repeated in twelve hours if necessary. For diaphoretic and diuretic purposes the following dose should be given in a wine glass of water and repeated every hour or two as is necessary:

℞	Tr. aconiti rad.	*m.*i—ij
	Spts. etheris nitr. . . .	*m.* xv
	Liq. ammonii acetat. . . q.s.ad.	ʒ ij.

A host of remedies have been suggested for local treatment. Carron oil often gives relief. It becomes offensive in a short time, however, and for this reason cotton-seed oil is better than linseed oil. Spirits of turpintine will stop the intolerable burning in a few minutes. In using this medicine locally, a good plan is to dip a piece of flannel in hot water and squeeze it as dry as possible, and then dip it in the turpentine and wring it again, and apply it to the erysipelatous surface for fifteen minutes or longer, according to the sensitiveness of the patient's skin. Ichthyol either in the form of collodion or mixed with vaselin may also be employed. Most patients will require a tonic, such as the tincture of the chlorid of iron, 20 to 40 drops every 2 to 4 hours. The disease is often associated with gastric disturbances so that the diet and stimulants ought to be under the immediate supervision of the physician.

Metatarsalgia and Its Treatment.—JONES and TUBBY (*Annals of Surg.*, September, 1898) do not agree altogether with Morton's theories of metatarsalgia. They attribute the pain which occurs when the fourth metatarsal bone drops out of the arch to pressure upon some nerve between the head of this bone and the skin, and not as Morton claimed to pressure produced upon the plantar digital nerves by their becoming caught between the head of the depressed bone and the adjoining bones. Collapse of the anterior arch, they say, would render the nerve less liable to compression in this situation. Moreover, in many cases, a firm grasp around the foot which raises the arch will relieve the pain. Flexion of the toes will also accomplish the same thing, this, too, raising the heads of the metatarsal bones. Manipulations of the foot other than direct local pressure rarely increase the pain. A callous spot is often found over the head of the depressed bone showing that pressure at this point is considerable. They, therefore, consider that the important factors are: (*a*) The proximity to the painful area of the communicating branch of the superficial division of the internal plantar; (*b*) the collapse of the anterior arch in most of the cases, and (*c*) the fact that the bulk of superincumbent body weight in walking on the toes is borne on the first and fourth toes.

The treatment which is recommended varies according to the degree of the trouble. If the difficulty is slight the treatment is largely preventive and consists in raising the inner aspect of the sole and heel, and wearing thick-soled boots so as to avoid pressure upon the painful spot. These should be made so as to give plenty of room about the metatarsals, while fitting snugly around the instep. Some patients obtain relief by putting a little pad of cotton, or India rubber, or cork inside the shoe just behind the head of the metatarsal bone. If the trouble is more severe, in addition to the measures recommended it is desirable to wear a firm leather band about the instep, which can be laced up so as to give the required support. Baths of hot and cold water, oleates of belladonna and morphin, and massage are useful. If the pain is very acute it is desirable that the patient remain in bed for two or three weeks to give the neuritis time to subside. If the nerve has become chronically inflamed it will be necessary to remove the head of the metatarsal bone. Other measures, such as resection of the nerve, use of the cautery, injections of carbolic acid, etc., are unsatisfactory. The head of the bone should be removed through a dorsal incision, and the patient should refrain from walking until the scar is firm.

Carbonic-acid Gas for Local Anesthesia. — BULLITT (*N. Carolina Med. Jour.*, September 20, 1898) has experimented with carbonic-acid gas as a means of producing local anesthesia. The gas is contained in a storage-drum under a high pressure, 1000 pounds or more. By its expansion when it is allowed to escape intense cold is produced. This is one of the methods of manufacturing ice. In order to produce local anesthesia the gas is allowed to escape through a small brass pipe to the end of which is fixed a fine hollow needle. If this is directed toward the skin a white spot is immediately produced just as when ethylchlorid is used. Ethylchlorid is very expensive, while the carbonic-acid gas costs but little, and the apparatus to contain it can easily be manufactured for three or four dollars.

For Lupus Vulgaris.—KACZANOWKI of St. Petersburg reports complete cures from applications of potassium permanganate which has a potent caustic action on granulation tissue. If there be crusts these are first removed in the usual manner by oil, etc. The affected area is then covered by a layer (2 to 5 millimeters thick) of the finely pulverized drug. If near the eye or nose these must be protected by a pad of cotton and a nasal plug which are removed on the following day when the secretion will have formed a crust with the permanganate. Absorbent cotton and a bandage complete the dressing. The one application destroys the granulations; the eschar comes off in about two weeks and cicatrization proceeds under simple antiseptic dressings, or an ointment containing nitrate of silver may be used to hasten the process. The treatment is painful but bearable.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed *exclusively* to THE MEDICAL NEWS will after publication be liberally paid for (accounts being rendered quarterly), or 250 reprints will be furnished in place of other remuneration. When necessary to elucidate the text, illustrations will be engraved from drawings or photographs furnished by the author. Manuscripts should be typewritten.

Address the Editor: J. RIDDLE GOFFE, M.D.,
No. 111 FIFTH AVENUE (corner of 18th St.), NEW YORK.

Subscription Price, including postage in U. S. and Canada.

PER ANNUM IN ADVANCE $4.00
SINGLE COPIES 10
WITH THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES, PER ANNUM 7.50

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

SATURDAY, DECEMBER 17, 1898.

THE GARRISONING OF OUR TROPICAL POSSESSIONS.

IN this week's issue of the NEWS we begin a series of articles on the above subject. The topic will be extended to cover not only the discussion of proper provision for our soldiers who are to be stationed permanently in these tropical islands, but will also include a discussion of the general sanitary measures that are necessary to make them healthful not only to the native population, but also to the large immigration of our own citizens who will doubtless seek these fields, so inviting for new and great financial enterprises. The series will be introduced by several articles trom the pen of Dr. Seneca Egbert, Professor of Hygiene and Sanitation in the Medico-Chirurgical College of Philadelphia, and the author of a work upon that subject. These will be followed by five articles having special reference to Puerto Rico by Dr. Azel Ames. Dr. Ames has already had experience in this island as general inspector of sanitation, and now goes there permanently as the Chief Medical Officer on the staff of General Henry, Military Governor of the island. The succeeding articles and their authors will be announced in due time.

THE PRESIDENT'S MESSAGE AND ITS MEDICAL SUGGESTIONS.

PRESIDENT MCKINLEY'S message to Congress contains the following significant words: "The sanitary problems connected with our new relations with the islands of Cuba and the acquisition of Puerto Rico are no less important than those relating to commerce, finance, and administration."

This assertion is at once a fitting acknowledgment of what sanitary science has accomplished in the past, and a quarantee that its sway shall be still further extended in the future. It is worthy of note that in a presidential message that is concerned with more important matters of state than have been discussed in a message for thirty years, a place should be found for questions of sanitation. It is an index of the prominent place that matters of public health have acquired in this last half of the century. We welcome it also as a just tribute to the unselfish work of the medical profession, which has made questions of sanitation so prominent by demonstrating that the prophylaxis of disease rests exclusively upon it.

The President renews his recommendation that provision be made for a commission of experts to study the situation and advise as to the best means of applying whatever the most recent advances in science can suggest for the protection of the health of our soldiers and citizens; security against the constant menace from the importation of yellow fever, under which our home country suffers will also have the attention of this commission. This suggestion is of course a most timely one and will, we feel sure, be acted upon at once. It is unfortunate, however, that circumstances are such that so important and pressing a matter should be compelled to undergo the delay necessitated by a special appropriation. There should be, there must be established soon, a national Bureau of Health to which, when such serious sanitary problems arise, the Executive may turn as naturally as he now turns to the head of the Treasury Department for the management of questions of finance. The need for such a medical department is constantly becoming more and more clear. Meantime, the Marine Hospital, as far as its powers can be made to extend, has done excellent work in these national sanitary questions. It is to be hoped that at this conjuncture too, its services will be employed as far as possible. For what-

ever tends to put the great problems of national sanitation into the hands of a regularly established bureau of health must be welcomed as an advance in the right direction, as a step toward what must inevitably come, a national department of public health.

HIGH BUILDINGS AND HEALTH.

The recent fire in one of the so-called "sky-scrapers" in the lower part of New York City again sharply directs public attention to the menace to life and property inherent in such lofty structures. With the utter inability of the present fire-department facilities to cope with a fire in these high buildings, or the fallacy of thinking that any so-called fire-proof building is really fire-proof, we have nothing to do. The holocaust of human lives that will some time, in the not distant future, be offered to the god of Mammon and the goddess of Negligentia, before whom municipal authorities, it is said, in this country at least are prostrate in perpetual adoration, concerns us much more nearly, but is not to our present purpose.

If the modern science of hygiene has demonstrated anything it is, surely, that sunlight is Nature's great bactericide. Six hours of exposure to direct sunlight will infallibly kill bacteria even as resistent as the tubercle bacilli. It is evident that in the past the preservation of humanity from even more prevalent disease than that from which it suffered, has been due to the pervasive influence of sunlight and its wonderful powers as a germicide. If the present tendency to erect high buildings on narrow streets is allowed to continue it will not be many years before the amount and duration of the sunlight capable of entering their lower floors and those of neighboring buildings will count for nothing. A greatly increased morbidity from zymotic disease among those compelled to work long hours in the rayless apartments of these structures where the sun practically never penetrates must therefore inevitably follow.

We venture to say that, even at present, respiratory diseases such as pneumonia and tuberculosis are far commoner among the workers on the ground floors shaded by such buildings than under normal conditions of air and sunlight. There is great danger ahead in this matter. The penalty for the capitalist's greed and the municipality's neglect will fall upon the unconscious and innocent employees. With the amount of territory at present in Greater New York there should not be the slightest necessity for these lofty towers. Let there be a limit to the building heighth then, and let that limit have such a relation to the width of the street on which the buildings are situated that ample sunlight, the God-given preserver of health, shall be secured.

THE SIX-DAY BICYCLE RACE.

Thanks to the careful attention given the matter by the Board of Health, this year's six-day bicycle race has come to a close without practically any of the extremely objectionable features, so manifest at previous contests, coming to the public notice. There were, we understand, on certain occasions quarrels between the contestants and their trainers, a lurking suspicion of persecution, and some complaints that food and drink were being tampered with. In a word, there were present the phenomena which inevitably supervene on brain anemia and the disturbed metabolism of nervous tissue incident to overwork, underfeeding, and the presence in the circulation of an overplus of the products of muscular exertion. The brain anemia seems to have been the prominent feature and the one most easily diagnosed. It was usually the direct result of incipient heart failure, and the men were compelled by the Health Authorities to abandoned the contest as soon as unmistakable and progressive symptoms of this condition became manifest, provided they did not yield promptly to judicious stimulation.

The very significant question presents itself, however, is it worth while that a certain amount of the energies of the Health Department of a great city like New York, where so many sanitary evils are crying out for correction, should be devoted to making an ill-advised six-day bicycle race less objectionable in the public eye? It is a mere money-making exhibit that carries with it great and manifold evils and does absolutely nothing for the healthful sport of bicycling. It has been condemned utterly by the best authorities on these matters.

There yet remains a number of features that make its repetition another year extremely inadvisable. It is the refinement of cruelty to allow human beings to work themselves into the state of haggard exhaustion that was so visible on the faces of the contest-

ants during the last days of the race. The rewards offered, the cheers and interest of the unthinking crowds, and finally the plentiful employment of the strongest known medical stimulants were utilized to arouse in the riders the willpower necessary to enable them to go on notwithstanding their pitiful physical exhaustion. We would not hesitate a moment to pronounce it unjustifiable cruelty if analogous means were employed to make animals do the same thing. The spectacle is anything but an elevating one, and the effect on the crowds who flocked to see it was undoubtedly degrading. Since there is no good reason for its occurrence, except the pecuniary interest of the managers, an enlightened public sentiment should be at once aroused to prevent its further repetition.

AN ANARCHIST'S SENTENCE.

LUCCHENI, the Italian anarchist, who murdered the Empress of Austria last summer in Switzerland, has been sentenced to penal servitude for life. The laws of the Swiss canton in which the crime was committed do not permit capital punishment or doubtless the death penaly would have been decreed. Public opinion would have demanded it. It is far better as it is, for surely no one with any clinical experience in mental diseases can doubt for a moment that the active agent in this extremely deplorable affair is not entirely responsible for his deed. The usual argument of those who insist on the severest possible punishment in these cases is that it will act as a deterrent upon the mentally unbalanced and keep them from putting any insane notion of theirs into action. Experience seems to show that exactly the opposite is the case. To take cranks seriously, to glorify their actions by solemn legal punishment, is in their eyes to make heroes and martyrs of them. Such action encourages rather than discourages imitation. The bathos of committal to an insane-asylum is the best deterrent. To deny their inspiration and their heroism before the world and attribute their action to its true cause, mental disequillibration, is the one thing above all that "cranks" dread; it brings would-be imitators to their senses better than any supposed punishment.

Medical opinion has advanced greatly since the death-penalty was exacted in Guiteau's case in response to the demand for a victim upon whom to wreak vengence. It is clear to our minds that if that trial were to be held at the present time the death-sentence would be the signal for strenuous protest on the part of those members of the medical profession best fitted by their experience to judge in the matter. The advance in medical opinion along these lines is noteworthy. It speaks well for that larger sympathy with mentally deficient or unbalanced humanity that began just a century ago, when Pinel, amidst the breathless suspense of all Paris which wondered what the result would be and portended untold evil, knocked the chains and gyves off the poor maltreated insane inmates of Bicêtre.

The profession and the public are learning to realize that the active agent in many a tragedy is much more to be pitied than to be blamed. Let us hope too that sad experience has taught us the necessity for precautions in those cases in which threats have been uttered. If our larger knowledge but lead to the prevention of these sad tragedies by the suggestion of effective precautions, even to confinement in an asylum, then indeed will the growth of our knowledge in mental diseases be doubly blessed in the humanitarian purposes it will serve.

BRAIN WEIGHT AND INTELLECTUAL CAPACITY.

A BELIEF in phrenology is by no means uncommon among the laity and we are sorry to say that even orthodox members of the profession sometimes show strange leanings toward a modified acceptance at least of the old doctrines on this subject. The conviction, however, that there is a direct ratio between brain weight and intellectual capacity is very widespread among the profession and thinking people generally. A very interesting article by Dr. Joseph Simms in the December number of the *Popular Science Monthly* disposes effectually of any foundation for such a doctrine. The heaviest brain on record, though the case is not well authenticated, was that of a London newsboy who was somewhat idiotic. Its weight was 80 ounces. The brain of Rustan, an ignorant undeveloped Scandinavian peasant, weighed 78.3 ounces, that of a dwarf Indian squaw 73.5 ounces. The heaviest brain among great men was Turgenieff's, the Russian novelist, which weighed 71 ounces. After him comes the distinguished Scotch physician, Dr. Abercrombie whose brain weighed 63 ounces, then General Aber-

crombie and our own General Ben Butler with 62-ounce brains.

The average weight of the human brain varies according to various authorities from the estimate of Austin Flint, who said 50.2 ounces, to that of Professor Krause, the anthropologist of Berlin, who said 55.4 ounces. Considerably below this average in brain weight were such distinguished men as Huber, the philosopher, Grotius the great commentator, Liebig the chemist, Babbage the well-known mathematician and inventor of the calculating-machine, Bishop the mind-reader, and finally, most notable of all, Gambetta the distinguished French statesman, whose brain weighed but 40.9 ounces. Gambetta died from a pistol shot, so that no lingering premortal process drained the normal brain substance of its nutrition. These figures, therefore, show the actual weight of his brain as it was in life.

The average weight of the brains of 60 famous men was 51.3 ounces, that of 10 idiots and 5 imbeciles that are on record, 59.2, a difference of 7.9 ounces in favor of the weak-minded. The explanation so often advanced for increased difficulty of parturition in our time, that with intellectual development the race is acquiring a larger skull, would seem according to Dr. Simms' data to be the theoretic evolution of some advanced obstetrician's inner consciousness. The skulls found in the Indian mounds are larger than the present average skull; those found at Pompeii are larger than the average Neapolitan's of today. May we dare hope that there will be no more theorizing on these two much "be-theoried" subjects without due regard to the facts?

LIFE INSURANCE FOR DAMAGED LIVES.

THE President of the New York County Medical Society in his recent inaugural address touched on a matter of extreme interest to physicians in general, the question of insuring damaged, or as they call them in insurance parlance, "substandard" lives, *i. e.*, persons whose health is in some way impaired and who would not under ordinary circumstances be accepted as risks by life-insurance companies. It has long seemed to thinking medical men that a field for the extension of insurance benefits without loss to the company existed in this direction. This discussion of the subject, therefore, is cordially welcomed because it comes quasi officially and is an index of present tendencies in life-insurance circles.

Medical men have long felt that among those rejected by insurance companies there are a number of people who constitute good risks and whose expectancy of life is not below the average, people with tubercular family histories yet healthy themselves, or with the personal history of some phthisical manifestations years ago but now in good health. Not a few of them are affected with a slight heart lesion, often with only a heart murmur (it is sometimes forgotten that the terms are not identical in meaning) but with never a symptom of disturbed compensation, or with an albuminuria without casts or some of the other not clearly significant manifestations for which insurance companies deem it wise to reject applicants.

Most medical men, too, have been of the opinion that the present system was unfair in certain ways. Actuary statistics of the expectancy of life of the whole population, are, we believe, used to determine premium rates, while policies are issued only on the select lives that have no defects and whose expectancy of life, therefore, at any given age is considerably greater than the average. It has even been said that the present profits of the life-insurance business and its ability to pay magnificent salaries was due to this fact. We are glad to think that this opprobrium, if it has any real basis in fact, is about to be removed.

From a purely medical standpoint we welcome the heralded innovation for two reasons. The consciousness of a provision for their families will be a remarkably steadying therapeutic agent for certain nervous patients whose neurotic symptoms manifested in functional heart murmur, or cyclic albuminuria, have in the past led to their rejection by insurance companies to the no small detriment of their state of mind and health. The second medical advantage certain to accrue from it is that the careful study of these damaged lives will build up scientifically the precious study of prognosis, so important in itself, so much studied by our medical forbears, but advance in which has not kept pace with the progress in other departments of clinical medicine.

MALARIAL NEPHRITIS.

THE careful study which, since the discovery of the malarial parasite, has been devoted to malarial

infections and their complications, has practically laid the basis for a scientific knowledge of the disease. Despite all the work done much remains to be accomplished. During the last year or two, exclusive of the contributions to our knowledge of the life history of the parasite, the most interesting progress has been made in the line of the pathologic changes induced in the kidneys by the elimination of the toxic products of the disease.

Hirsch, the great medical geographer, relying on the statement, supported as it seemed to be by statistics, that Bright's disease was not common in India or Brazil though malaria was there endemic, expressed the opinion that there is no etiologic connection between malaria and nephritis. Further study, however, has shown that this opinion is not entirely true.

Malarial nephritis has been found to be much more frequent than was formerly thought. As usually happens in medical matters, however, the pendulum of medical opinion swung a little too far. Exaggeration of the frequency and seriousness of nephritis complicating malaria took the place of former failure to recognize it. Albuminuria during malaria has been so commonly found when carefully looked for that the conclusion has very naturally been entertained that actual kidney lesions must be frequent. Two recent thoroughly conservative reviews of the question do not support this conclusion. One of them is Dr. Thayer's article on "Nephritis of Malarial Origin," in the November and December numbers of the *American Journal of the Medical Sciences*. It must be considered as expressing the views of the Johns Hopkins School in the matter; and of late years it is to the latter that the profession in this country has learned to look for the best scientific opinions on malarial questions. The other discussion of malarial nephritis is from the Roman School, by Dr. Giacamo Rem-Picci in *Policlinico*.

Dr. Thayer notes the finding of albuminuria in malarial fevers in 46.4 per cent. of the cases treated at Johns Hopkins. Acute nephritis occurred in only 1.7 per cent. It is interesting to note how much severer on the renal functions and apparently also on the kidneys themselves is the effect of that type of malaria which is at present receiving so much attention, the estivo-autumnal form. Of the cases infected with this form of the malarial parasite albuminuria occurred in 58.3 per cent.; acute nephritis occurred in 4.7 per cent. of the cases treated in the wards, the severer infections, and in 2.3 per cent. of all the cases seen.

Dr. Rem-Picci, at Rome, has been very careful to exclude all cases except those in which the albuminuria was observed to set in during the malarial infection. There are so many other possible sources of kidney irritation that he very properly considers that care in this matter is most necessary. He has evidently excluded all cases too, in which only traces of albumin were observed, for he has found albuminuria in only 6 per cent. of the cases. In more than 7000 cases of malaria in the hospitals of Santo Spirito and San Giovanni, at Rome, he has found acute nephritis in 80 patients, just about 1.1 per cent. It is very interesting to note that these figures agree almost exactly with Dr. Thayer's, for among white patients, as we note farther on, he found acute malarial nephritis in 1.1 per cent. of his cases. He does not attribute the nephritis so much to the malarial parasite itself or any toxins secreted by it as to the toxic influence of the unusual metabolic products that arise from altered physical conditions during the attacks and which must be eliminated afterward. This is based upon the findings of Bacelli, who has shown that after a "chill" there is an increase in the specific gravity of the urine, and certain products of abnormal tissue-metabolism are demonstrable in it. Dr. Rem-Picci considers that in healthy individuals with normal kidneys this will not cause nephritis though it does in the less resistive. A curious confirmation of this opinion seems to be found in Dr. Thayer's observation, that while nephritis occurred in white patients in only 1.1 per cent. of the cases of malaria, it occurred in negroes in 7.3 per cent., "figures," he adds, "which are quite in keeping with the clinical fact often noted at Johns Hopkins, *viz.*, that the colored race is much more susceptible to renal disease than the whites."

On the whole acute nephritis cannot, as a rule, be attributed directly to the presence of the malarial parasite, and the question of chronic nephritis is so involved with other factors that scarcely more than the suspicion of the causal relation of malaria to it can at present be entertained.

At Rome medical men are perfectly outspoken in advocating the use of quinin in malaria, even in the cases complicated by nephritis. A recent editorial opinion in the *Journal of the American Medical Association*, based absolutely, so far as we can see, on no good or convincing reason, is calculated to do much harm. The journal advises against quinin. On the contrary, at Rome, where the profession has unusual opportunities for studying this malady, quinin, in all cases, is invariably considered indispensable. Cases are on record in which albuminuria and hemoglobinuria have increased when quinin was for a time withheld and later have diminished and finally disappeared with the malaria when the quinin treatment was energetically pushed.

ECHOES AND NEWS.

St. John's Guild of New York.—By the recent gift of $32,000 this Guild is enabled to construct another floating hospital for the benefit of the children of the sick poor. It will be ready for use next summer.

Major Booth Resigns.—Major Burton S. Booth, Surgeon of the 203d New York Volunteers, has resigned his commission in the army and returned to his home in Troy, N. Y., where he will resume his practice.

Dr. Sanger Brown—A Correction.—Attention has been called to the statement made in the last issue of the MEDICAL NEWS regarding Dr. Brown's resignation from the faculty of Rush Medical College, Chicago. The chair which he formerly held, and from which he resigned, was that of Medical Jurisprudence and Hygiene.

A Case of Lacerated Spleen.—A helper in the Bellevue Hospital Medical College died recently in the hospital of a disease which the physicians had not been able to diagnose during his two-month's sickness. Dr. Herman M. Biggs performed an autopsy, and discovered that the chief cause of death was a laceration of the spleen; cause of the latter unknown.

The Sick and Dead at Manila.—During the last week there were reported 1991 sick at Manila, against 1922 during the preceding week. The deaths were: From typhoid fever, 1; dysentery, 3; melancholia, 1; suicide, 1; and smallpox, 3. A convalescent hospital is about to be established on Corregidor Island, in charge of Major Owen. It will contain 100 beds.

Typhoid from Bad Milk.—There is an outbreak of typhoid fever in an uptown district of New York City bounded by Mott and Walton avenues and 138th and 152d streets. There are seventeen cases in the district, and all but four of them arose from infected milk sold by a grocer in the neighborhood; the rest, it is said, are cases of men who brought the disease from some of the army camps.

"Dr. Therne," by H. Rider Haggard.—Under the above title this popular author has just published a book dedicated to the Jenner Society in which he sets forth in characteristic style the lamentable consequences which he foresees must follow the recent antivaccination legislation in England. The humiliation and shame which overtake "Dr. Therne," who has deserted his principles and gone over to the antivaccinationists, are depicted with tragic force in the closing chapter.

Obituary: Salmon P. Cahen, M.D.—The Medical Board of the West Side German Dispensary of New York and the faculty of the New York School of Clinical Medicine, at a joint meeting, recently adopted resolutions upon the death of their colleague, Salmon P. Cahen, M.D., former secretary of the medical board, expressing appreciation of his nobility of character, his scientific attainments, and his devotion to the sick poor. It was resolved that his death was to them an irreparable loss.

"The Medical Age" and Osteopathy.—For some time it has been thought by the parties interested and by their friends that the suit begun by an osteopath against the editor of *The Medical Age* was only a bluff and an advertising ruse, especially as the plaintiff failed to provide security for the costs of the action. It appears, however, that the security has finally been given and that the case will shortly come up for trial. We bespeak for the defendant the sympathy of the entire medical profession of the country and shall watch the progress of the case with no little interest.

The New York German Medical Society.—Die Deutsche Medicinische Gesellschaft celebrated its thirty-eighth anniversary with a banquet at the Arion Hall, Saturday evening, December 10th. Dr. Abraham Jacobi presided most felicitously as toastmaster, and by his happy presentation of the toasts called forth most spirited and interesting responses. An interesting feature of the occasion, and somewhat unusual at medical society meetings, was the presence of the doctors' wives who lent a charm and grace to the occasion, especially in the social features which followed the banquet.

The New Jersey Sanitary Association.—The twenty-fourth annual meeting of this society was held at Lakewood, December 9th and 10th. The president, Vernon L. Davey, superintendent of the East Orange public schools, gave an address on "The Relation of the Schools to the Health of the Community." "It is coming to be felt by practical educators," said Mr. Davey, "that there should be some sort of supervision of the physical side of the pupil—not merely in the way of giving a few minutes daily to light calisthenics, but in securing a frequent, professional observation of the pupil's physical condition."

Solvent Action of Water on Metals.—Robert Meldrum in a recent number of the *Chemical News* reviews the generally accepted opinions as to the solvent action of water upon copper and lead vessels and pipes, and details some personal experiments. It confirms the opinion that a "soft" water dissolves much more lead than a "hard"

water. A slight amount of carbonic acid does not add to the solvent action of the water but the presence of large amounts of CO_2 causes the water to take up lead in considerable amounts. The importance of this fact in connection with the tubes and fittings of so-called "soda-water" apparatus is evident.

Suicides in Italy.—Suicides in Italy during the year 1896 show an increase of fifty per cent. over the ten preceding years. The total reaches 2000, which gives a mortality of 6.41 per 100,000 inhabitants; of these 2000, 1404 were men and 596 women; 813 were married, 884 single, 177 widowers, and 61 widows. Three causes of the increase are given: the greater difficulty of earning a livelihood, the growing burden of taxation, and the spread of education, which in many cases leads to much unsatisfied ambition. The districts where suicide was most prevalent are those where education is most developed; in the provinces where education is, if anything, neglected, the proportion attained is scarcely two or three per 100,000.

Temporary Ectopia Cardis.—The *British Medical Journal* recalls Surgeon-General Jameson's story at the Virchow dinner of the officer who, wounded in the region of the heart, received no wound of the heart, perhaps because that valued organ was at the moment "in his boots" and the MEDICAL-NEWS story of Ex-Governor O'Farrell of Virginia, who attributed his escape from fatal injury under like circumstances in our Civil War, to the fact that "his heart was in his mouth" and suggests that temporary ectopia cardis would seem to be a not infrequent condition among warriors "when the drums begin to beat." All that has been wanting to set these cases on a proper medical (or is it surgical?) footing was a scientific title. Now they have it.

Continued Decrease in the Population of France.—The official reports of the Ministry of Commerce on the French population have just been issued for the year 1897, during which the total number of births was 859,000, as against 865,000 births for the year 1896. In military and colonial circles the apprehension caused by this decrease is further emphasized by the discovery that the French population contains a smaller number of men and women of what are termed the able-bodied ages, namely, from fifteen to fifty-years in the case of men, and to forty-five in the case of women, than it did thirty years ago. The number of men capable of bearing arms, which has been stationary for forty years, shows a slight falling off, even after due allowance is made for loss of territory.

Dinner of Medical Alumni.—The alumni of the College of Physicians and Surgeons, New York, had a dinner on the evening of the 8th inst. Drs. Gibbs and Lehmann, alumni who died in the late war, were eulogized. Dr. Charles McBurney, in the course of a diverting speech, said: "I am perfectly willing to admit that the College of Physicians and Surgeons is the finest and best-equipped plant for medical instruction that was ever erected; that it is reported to have the most capable, skilful, and learned corps of instructors that were ever gathered together; but as for me, I am of the old school." From this it is evident that he is far from being in sympathy with the new and so-called "advanced" ideas of medical teaching.

Sir William Jenner's Death.—Sir William Jenner, the distinguished English medical man, died December 12th. He was President of the Royal College of Physicians of London from 1881 to 1889 when he retired from the practice of his profession. He had been Physician in Ordinary to the Queen since 1862 and to the Prince of Wales since 1863. His work on the differentiation of typhus and typhoid fever is well known. In 1894 the Maxon Medal of the Royal College of Physicians, which is given for distinguished services in clinical medicine, was conferred upon him. Sir William Jenner was nearly eighty-four years old, having been born in 1815 in Chatham, and began his medical career as a general practitioner. His first hospital appointment was as Surgeon Accoucheur to the Royal Maternity Hospital.

The Meeting of the American Society of Naturalists.—The principal meeting of the American Society of Naturalists which, as we have announced before, is to have a series of meetings in New York City during Christmas week, will be held at Schermerhorn Hall, Columbia College on December 29th. An address of welcome is to be delivered by President Low and then short papers are to be read on "Advances in Methods of Teaching" by the following heads of university departments with special reference to their branches; Zoology, Professor F. G. Conklin of the University of Pennsylvania; Anatomy, Professor George S. Huntington of Columbia University; Physiology, Professor W. T. Porter of the Harvard Medical School; Psychology, Professor Hugo Münsterberg of Harvard University; Anthropology, Dr. Franz Boas of Columbia University; Botany, Professor W. F. Ganong of Smith College.

"Archives of Pediatrics."—The December number of this journal closes the fifteenth year of its existence. With the beginning of the new year E. B. Treat & Co. of New York become the sole proprietors of the journal, having purchased the interest of its founder and former owner, William Perry Watson, M.D. The present editorial management, however, continues the same. In closing the fifteenth year of its existence the editor indulges in some reminiscences upon the growth of that specialty. He says: "The launching of a pediatric journal fifteen years ago was a difficult and hazardous undertaking and its success was only achieved by the energy and determination of its founder. Without a pediatric society in the land, or even the section of a society to stimulate men to special work; without a full professor of pediatrics in any medical college, or any organized body of teachers or workers, the difficulties of maintaining a special journal were indeed great. The *Archives* has been a potent factor in combining and solidifying the diffused elements which now go to make up the specialty of pediatrics."

Shorter Hours for Drug-Clerks.—The occurrence during the past week of the substitution in a prescription of

atropin for morphin, which was noted in last week's issue, was followed by serious, but fortunately not fatal, symptoms. Attention is called to it once more for the purpose of emphasizing the necessity for the strictest enforcement of the regulations already existing as to short hours of service for drug-clerks. There can be no excuse for a mistake committed because weariness supervened after too long service, the resultant inattention causing fatal substitution. The clerk in the prescription department must during hours of service ever be thoroughly wakeful. His position is in a lesser degree as important as the train-despatcher or switch-tender and lives are often dependent on careful and supremely intelligent service. The Druggists' League for Shorter Hours has a ten-hour bill to be introduced into the next New York legislature and it is to be hoped that the united efforts of medical and druggist influence will bring about its passage. The movement has our heartiest sympathy and its object our most cordial commendation.

Preparations for Burial after Only Apparent Death.—An inmate of the Dodge City Soldier's Home in Kansas is said to have been pronounced dead by the physicians and to have been prepared for burial. He revived after having been put in his coffin, and is now said to be on a fair way to recovery. He has no recollection, it is reported, of any sensation during the time he lay apparently dead except a confused feeling of hunger and a distinct iciness about his feet. This is one of those cases of preparation for burial of the living which are reported every now and then, usually from some obscure out-of-the-way place. Investigation practically always shows that they are a figment of some reporter's vivid imagination. They disturb very seriously the peace of mind of certain nervous people and are a source in this way of a good deal of needless suffering. We have written to the superintendent and the medical attendant of the Dodge City Soldier's Home, and shall report the real facts of the case to our readers if it is possible to obtain them. We shall always be glad to report the exact details of such cases, and especially of the correction of errors in this matter so common in the daily press.

The Truth about Vaccination.—Dr. Bizzozziro, in a recent lecture delivered at Rome, recalled strikingly to his audience the success of vaccination in Germany. He said: "Germany stands alone in fulfiling in great measure the demands of hygiene, having in consequence of the calamitous smallpox epidemic of 1870–71 enacted the law of 1874 which 'makes vaccination obligatory in the first year of life and revaccination also obligatory at the tenth year.' What was the result? With a population of 50,000,000, having in 1871 lost 143,000 lives by smallpox, she found by her law of 1874 the mortality diminished so rapidly that to-day the disease numbers only 116 victims a year. These cases, moreover, occur almost exclusively in towns on her frontier. If it were true," continued Professor Bizzozzero, "that a good vaccination does not protect from smallpox, we ought to find in smallpox epidemics that the disease diffuses itself in the well-vaccinated no less than in the non-vaccinated countries. But it is not so. In 1870–71, during the Franco-German war the two peoples interpenetrated each other, the German having its civil population vaccinated optionally, but its army completely revaccinated, while the French (population and army alike) were vaccinated perfunctorily. Both were attacked by smallpox; but the French army numbered 23,000 deaths by it, while the German army had only 278; and in the same tent, breathing the same air, the French wounded were heavily visited by the disease, while the German wounded, having been revaccinated, had not a single case.

Report of the Austrian Commission on Bubonic Plague.—The Imperial Academy of Science of Vienna has given out the report of the above commission. It will be remembered that the lamented Dr. Hermann Müller, who recently fell a victim to the plague at Vienna, was a leading member of this commission and executed and described the principal scientific work. According to him, the experience gained during the last epidemic shows the development of the bubo to be one of the first symptoms of the disease and to precede the earliest appearance of the violent disturbance of the nervous system. Clinical observation leads strongly to the conclusion that the disease originates in an infection through the skin, which remains localized for a time. The general affection afterward develops from this center. Apart from primary infection, pneumonia, which unquestionably enters through the respiratory canal, it is probable that in no case is there an absence of glandular swelling, although in many instances the presence of the primary bubo cannot be clinically ascertained with certainty. Dr. Müller's colleagues were unable in three cases which they dissected to discover the characteristic signs of the primary bubo. The dissections proved, however, that in certain cases where the swelling was slight and painless, the examination of the patient by palpation or touch had failed to establish the presence of a bubo which, nevertheless, existed. Dr. Müller considers it probable that, in many cases, the infection may retain its local character during the whole course of the disease and never become general. The milder character of the disease in individual cases cannot with any certainty be attributed to mere localization, however, as instances of the less malignant form also occur where the infection is general. The time at which the infection becomes general cannot be recognized from the external symptoms. From these circumstances it must be concluded that the course and termination of the disease are not to be inferred from the mere fact that the infection has remained localized or become general. The positive or negative result of bacteriological examinations is alone decisive. He expresses himself strongly against the experimental puncture of the bubo, and is still more opposed to larger incisions and the cleaning out of its contents. A patient, he says, does not die because he has bacilli in his blood, and does not recover because of their absence. On the contrary, the question whether the organism will triumph over the disease depends upon the degree of its natural power of resistance to the toxins of the bacillus. There can be no doubt that general infection has occurred in patients who have recovered, and it is even probable that there have been many such cases.

SPECIAL ARTICLE.

THE PRESENT STATUS OF OPINION UPON THE USE OF QUININ IN MALARIA.

QUININ has long been recognized as a thoroughly efficient remedy for malaria. At the same time there has always existed an undercurrent of feeling that it is more or less harmful to the human organism. This feeling has persisted despite the extensive use of quinin for centuries and despite the fact that except where idiosyncrasy existed it was usually impossible to point out definitely any unfortunate effects from its adminstration. This feeling of suspicion toward the drug corresponding closely to the very similar feeling with regard to the use of mercury in syphilis, has had its periods of dominence in medical history. Notwithstanding the fact that the action of quinin is no longer the mystery that it was before Laveran's discovery of the plasmodium malariæ, we seem about to enter on such a suspicious therapeutic period at the end of the enlightened Nineteenth Century.

We now know that quinin acts by its germicidal power over the plasmodium, and need not appeal to any indefinite theoretic antiperiodic or antifebrile action to explain its prompt action on malarial paroxysms, yet there is in the air a spirit of opposition to the drug that is liable to do a good deal of harm. Of late this opposition has taken the form of warnings against the use of quinin in suitable quantities for the treatment of the estivo-autumnal type of malaria. This form of malaria which only recent study has separated from the general class of intermittent fevers is acknowledged by all observers to be especially obstinate to treatment. All the authorities on the subject, however, who draw their knowledge from clinical experience and not from an inner consciousness are agreed that quinin is the one remedy absolutely necessary for the treatment of the disease, and that to accomplish any results the drug must be pushed vigorously and fearlessly and this despite complications that may be present.

. . . . . .

Professor Koch started the present reaction against quinin by stating after his return last June from German East Africa that he believed that quinin was used in too large doses in the treatment of malaria, especially in the tropics (it is there that the estivo-autumnal type of malaria abounds). He considered it proved to his mind that the well-known and much-dreaded "black-water fever" of the tropics, malarial hemoglobinuria, was practically always due to the excessive administration of quinin. This declaration of Professor Koch's had an unfortunate effect it is said even in our own army during the recent war. Some of the men refused to take quinin as a prophylactic, others stricken with malaria refused to take the drug as a remedy, or at least objected to its exhibition to them in doses sufficient to secure prompt and effectual results. Even some medical men were discouraged from prescribing as much quinin as they might otherwise have employed because of Koch's declaration.

It is of interest then to note that from all those having really extensive clinical experience in the matter of malaria Koch's views have called forth decided protest. Here and there some one with but small experience of malaria, or perhaps none (in which of these two classes we shall include the writer of a recent editorial in *The Journal of the American Medical Association* we do not know), has expressed agreement with Koch's opinion in the matter. The voice of our own Southern medical men, of the English medical men in India, and of the medical men of Brazil and of Italy have been as a unit against Koch. Dr. W. H. Crosse, recently the chief medical officer to the Royal Niger Company, the great English commercial and exploring company of Central Africa, discussed Koch's statements as to quinin and its etiologic relation to "black-water fever" at the opening meeting for the present scholastic year of the Guy's Hospital Physical Society. He has had a very large experience with tropical malaria, especially with the African forms of it, and is very outspoken as to Koch's imprudent jumping at unjustifiable conclusions in the matter of quinin intoxication. He has had "black-water fever" himself, a privilege not accorded to many foreigners whom the gods destine for long life, and is assured that quinin stands in no sense in a causal relation to it. The best proof of this is that the black-water fever occurs only in certain well-defined parts of the country, though quinin in used unsparingly throughout all parts of Africa. Another convincing consideration is that even in the midst of the genuine malarial hemoglobinuria the only remedy that can be depended on is quinin.

Koch was not the first by any means to call attention to the fact that quinin sometimes causes disintegration of the red blood-corpuscles. This fact had often been noted and was known to be an idiosyncrasy to quinin to which certain people with peculiarly susceptible red blood-corpuscles are liable. Laveran treats the subject very practically after considerable experience with it in Northern Africa and suggests the use of another of the cinchona alkaloids, the sulphate of cinchonidin, in such cases, but is not able to advise a stoppage of "bark" treatment.

. . . . . .

The estivo-autumnal type of malaria is especially intractable. It does not yield promptly to quinin, as do the other forms of the disease, but quinin is, nevertheless, in the eyes of all the authorities, our sheet anchor in its treatment. It is the form of malaria which is most liable to be complicated by nephritis, but the occurrence of this or of simple albuminuria does not constitute a contraindication to quinin. Brun and Laveran describe a form of intermittent albuminuria which is benefited by quinin. Rem-Picci of Rome in a recent series of articles on malarial nephritis in *Policlinco* has expressed his views on this matter very forcibly and considers that the renal lesions will be inevitably progressive unless quinin is administered in large doses without delay. Our own Osler says, "In an active malarial infection (no matter what the complication) the patient runs less risk with the quinin." It is interesting to note that he has "never seen a case in which black-water fever developed as the result of the use of the drug."

The files of the Indian and Brazilian medical journals

contain a number of protests against Koch's unwarranted deprecation of quinin and the harm it is liable to do if taken seriously. The good story from the Roman Hospital that was told last week in our editorial columns seems, as was said, almost too apt and too timely to be true, but it illustrates very forcibly Italian opinion as to the use of quinin, and especially of the necessity for pushing it, in the depressed conditions that result from estivo-autumnal infection. The intravenous injections of quinin introduced by Professor Bacelli are growing, not decreasing in favor. Certain remedies act as very helpful adjuvants to quinin in certain cases of the estivo-autumnal type, though quinin itself is practically indispensable. Among the adjuvants practically all are agreed that opium is the most useful. Employed as Professor W. H. Thomson suggests (see page 777) in the form of camphorated tincture, it is undoubtedly tonic and stimulant and gives with the quinin results that that very useful drug would not give alone. Nothing can, however, replace quinin in the treatment of even estivo-autumnal malaria, so that there is every reason on good clinical authority to discourage the feeling at present existing in certain quarters, that it is not indispensable and may do harm.

SELECTED ARTICLE.

A FEW FRIENDLY BACTERIA.

The following conversation, overheard some months ago, may be of interest at the present time:

A few friendly Bacteria were drinking coffee after having dined together at the Royal Intestine Club one evening, when the Diphtheria Bacillus remarked to the Typhoid Bacillus: "Typhy, old man, you are one of the lucky devils; business goes along well with you, while we fellows see our splendid old-established houses crumbling before the modern school. Now, there is poor old Smallpox. I have heard Amebic Dysentery and his grandfather Cholera say they remember when Smallpox did nearly all the business on the Continent."

Over by the window, reading *The Anti-Serum Gazette*, sat Tubercle Bacillus. You could see that in his younger days he had been quite a fine-looking fellow. He rose and, approaching the group, said: "Well, boys, how is business?" "Pretty good," said two or three. "Elegant," said Measles, in his weak, piping, impudent voice. "I see, Diphtheria, my boy," continued Tubercle Bacillus, not noticing Measles, "England is still with you. She will not accept Antitoxin; they are weakening, though, I am afraid. Now, I have made it a rule when these investigations are too searching to get out of the way for a little while by taking up business somewhere else. Why, one day Staphylococcus, who is now in business with me (clever all-round fellow he is, too), came running into my office and said: 'Have you seen that Koch has definitely discovered you?' 'Yes, I saw that,' I replied quietly; 'but don't worry. And, boys I say to you, don't mind being seen. In my late unpleasantness with Koch over the Tuberculin affair, I was sorely put to it, but one day I called Streptococcus and said that he and Staphylococcus must transfer the bulk of my business from the lungs to the peritoneum, and that I wanted my own men at first to be put in charge of the new place of business, and that later Strepto and Staphylococcus and their men could take hold. "Well, you would be surprised how nicely business is going on there. I have been thinking seriously of giving up the lungs altogether."

"It's all right," said Typhoid, "for you and Diphtheria to talk of shifting your business. Now, I can do business in but one place, and they seem to be getting on to me there fast. It was evident that Typhoid was depressed and thought that his business looked gloomy; he, however, called the servant, Ptomain, to take the orders for drinks. Tubercle and Typhoid ordered milk punches, Typhoid adding that he wanted a dash of Woodbridge Antiseptic, which he found improved him so much. "Or, no," said he; "give me a bottle of Aerated Schuylkill Water. That always improves me."

"What are you grumbling about, Typhoid?" said Yellow Fever. "You who have no port restrictions ought to be happy enough now that war is declared." "You don't say so," said Malaria; "that makes things look up all around." Malaria was an Italian by birth; he had never been cultivated, however, and, being a foreigner, his methods of business were a little obscure, even to Typhoid, who at one time was supposed to be in partnership with him. "I have it," said Typhoid. "Let us watch the medical appointments, and if they are what we want, Yellow, and you, Malaria, and I will go to Cuba, and see what we can do." "There is not a name on the list I ever heard of, and I'll bet," continued Malaria laughingly, "not one of them has ever heard of me, much less seen me. But they all know about Quinine," he added dolefully. "Never mind," said Typhoid, "we can fool them together on the temperature charts. I will write a private letter to Johns Hopkins Hospital and ask if they have any objection to Messrs. Malaria and Typhoid doing business together for a few weeks."

The conversation herein related was overheard by Bichlorid and his brother, Calcium Chlorinatus, and the young fellow Formaldehyd, also Quinin, who were doing detective duty in the interest of the United States Government and the army. When the appointments to Cuba came only Quinin was appointed, and the rest were kept at home to do hospital duty.—DR. CAMAC, *N. Y. Times*.

CORRESPONDENCE.

A CASE OF XEROSTOMIA AND ITS CURE.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—I read with much interest the article on "Dry Mouth" by Dr. Lartigau in the MEDICAL NEWS of October 29th, as I have been wrestling with a case of that kind which I think can now be called completely cured. The case is as follows: Mrs. A., married, fifty-six years of age, born of Hebrew parents in Alsace, has resided in California since the early days, where she has raised a family of healthy children. She has always been healthy and robust, and now weighs 170 pounds, al-

though she has been *sans* teeth of any description for the last fifteen years. She is quick and nervous in action and manner. In May, 1897, she consulted me with reference to an extreme dryness of her mouth, which had been troubling her then for about four months, and which kept her constantly chewing to try to relieve it. She said it came on suddenly after an examination of her mouth for the purpose of having a set of teeth fitted, but which she was disappointed in getting.

I tried several remedies without appreciable effect, but on advising her to keep smooth pebbles in her mouth several hours a day she experienced marked relief. I advised the wearing of artificial teeth, therefore, as the best method of obtaining permanent relief. In August, 1898, she had a double set of teeth made, and since wearing them she has not had the slightest symptom of the trouble that had been harassing her constantly for twenty months.

M. W. WARD, M.D.

WOODLAND, CAL., December 1, 1898.

LYCOPODIUM SPORES IN URINE.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—Erroneous interpretation of foreign bodies in human secretions and excretions is a very extensive subject, and I should not add to the literature were it not for the fact that in the present instance the cause of error was a substance that might be supposed to be familiar, and the persons misled experienced microscopists. One can hardly be surprised if men without training in microscopic work mistake pitted cells for tube-casts, spiral ducts for parasites, etc., but modern biologic training should prevent such errors as the one described below.

While working at Sternberg Hospital, Chickamauga Park, last summer, a specimen of urine was brought to me from another hospital, with the following history: The urine came from a female nurse, sick with a mild fever. It contained a small amount of albumin and a fine granular sediment, and in the latter were always bodies which up to that time had not been positively identified. The gentleman who brought the specimen was a specialist in microscopy, appointed by the Government for carrying on laboratory diagnostic work. The bodies were unknown to the regular army surgeon-major, and the several volunteer surgeons in the hospital; they were seen by three experts in bacteriology, all original workers of international reputation, and one at least with training in general biology, without any near guess at their nature. The specimen then went the rounds of several pathologic laboratories with similar results. An ex-professor of pathology who claimed to make special studies in cell-degeneration, and who felt competent to teach that the malarial parasites are degenerated blood-corpuscles, asserted the bodies were degenerated bladder-cells. Many thought the bodies were animal parasites, and a government official, well-known as a microscopist, advised that the specimen be sent to a parasitologist, now in Europe, for identification. The bottle came to me because it was thought by some the bodies were the same as those I reported some years ago from the bladder of a man.

I found bodies in the urine which I at once recognized as vegetable spores of some kind, probably lycopodium, and from the number present thought them due to accidental contamination. I was assured by the physician they were the bodies in question, and were always in the urine in similar numbers as it was passed. A catheter had not been used. I could not at the time obtain lycopodium for comparison, but when I did was able to satisfy myself as to the identity of the spores. In the meantime my suggestion that the contamination depended on a dusting-powder proved to be correct, a powder containing lycopodium being used for some irritation of the labia. A description and illustration of the bodies does not seem necessary, as they can be obtained in any drug-store.

Occasional pollen grains or spores are not uncommon in specimens of urine sent from bedrooms, and their general appearances should therefore be known by those who have to examine urine. As with other contaminations, they can be excluded by taking the specimen with a catheter, or, in the case of a male patient, by seeing it passed.

GEORGE DOCK, M.D.

UNIVERSITY OF MICHIGAN,
ANN ARBOR, MICH., December 10, 1898.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

ANNUAL REPORT OF THE STATE BOARD OF HEALTH—NEW BUILDINGS OF THE UNIVERSITY OF PENNSYLVANIA—HOSPITAL BEQUEST—ANNUAL DINNER OF THE RESIDENT AND EX-RESIDENT PHYSICIANS OF THE PHILADELPHIA HOSPITAL—JEFFERSON MATERNITY DOLL-SALE—PERSONAL NOTES—INSTRUCTION IN CONTAGIOUS DISEASES—HEALTH-BOARD STATISTICS.

PHILADELPHIA, December 13, 1898.

THE fourteenth annual report of the State Board of Health has just been made public and contains not a few points of interest. After relating the results of the water-supply investigation and detailing suggestions for the improvement of the supply, as related in the MEDICAL NEWS a few weeks ago, the report takes up the matter of infectious diseases which were prevalent in the State during the last year. Five outbreaks of smallpox have occurred during the year, with but two deaths in a total of twenty-four cases. Two of the cases occurred in Philadelphia and, the authorities believe, may have been brought from the South by means of cotton, as the cases occurred among cotton-mill operators. Anthrax occurred in four counties of the State, and seems to be less rare than it is generally believed to be. There have been thirty-one outbreaks of diphtheria this year as against sixty-one during 1897, in connection with which the assistance of the Board was asked. Scarlet fever appeared at nineteen different points and there were twenty-nine outbreaks of typhoid fever as compared with seventeen last year. The local epidemic of typhoid fever confined to a certain section of the city seems to have been due to a defective sewer, which poured its contents into Wissahickon Creek, just above the intake of Queen Lane reservoir, which supplies the infected portion of the

city. A soldier from Porto Rico had what was probably yellow fever, the only case occurring in the State. There are several cases of leprosy in the State and one supposed case in Philadelphia.

The report concludes by calling attention, among other things, to the illegal practice of medicine, registration of graduates and licentiates in medicine, and to legal opinions and decisions.

The new laboratories of pharmacy, physiology, and pathology of the University of Pennsylvania will be begun in the spring and a committee of twelve, with Dr. J. M. Baldy as chairman, has been appointed to aid in raising the necessary money, some $300,000. An appeal is to be made to the alumni of the Medical Department and it is thought there will be no difficulty in securing the money from them as of 11,000 graduates there are probably 6000 now living.

A unique bequest, which is on exhibition here, has been made to the Delaware Hospital at Wilmington, in the shape of a handsome set of silver presented by employees of the Pennsylvania Railroad to Henry H. Carter, a division superintendent, and bequeathed by his widow to the hospital to be sold, the proceeds being used to maintain a free bed for railroad employees.

The Association of ex-Resident and Resident Physicians of the Philadelphia Hospital held its twelfth annual dinner last Tuesday, December 6th, at the University Club. Dr. J. Chalmers Da Costa, Chairman of the Committee of Arrangements, acted as toastmaster and toasts were responded to by Drs. William Osler of Johns Hopkins, Theodore Diller, J. William White, Horatio C. Wood, Alfred Stengel, Charles S. Potts, Joseph T. Buxton, and Richard C. Norris. A letter was read from Dr. Alfred Stillé, the President, who was unable to be present. About seventy members were present at the dinner.

A sale of dolls was held at the Stratford Hotel on Friday and Saturday last for the benefit of the Jefferson Maternity. A feature was "the old woman who lived in shoe," the shoe in question having been used for the same purpose at the Sanitary Fair held in Logan Square during the war (1864).

Dr. George M. Stiles of Conshohocken has been appointed by Governor Hastings a trustee of the State Hospital for the Insane at Norristown.

Dr. A. Graham Reed, aged sixty-one years, died of pneumonia last week. He was a graduate of the University of Pennsylvania and served as surgeon during the Civil War.

Dr. Thomas Leidy Rhoads, who recently received appointment as Assistant-Surgeon in the United States Navy, has resigned.

The local Board of Health has had quite a wrangle over the question as to whether advanced medical students should or should not be admitted to the wards of the Municipal Hospital for the purpose of studying contagious diseases. The Women's Medical College and the University of Pennsylvania recently asked for the privilege of sending students to the hospital for such purpose, and in view of these requests the following resolution was introduced:

Resolved, that the physician in charge of the Municipal Hospital be authorized to give instruction to ward classes in said Hospital, under such regulations as he may formulate, and which shall be approved by the Director of Public Safety and the Sanitary Committee of the Board of Health, provided that such instruction may be discontinued at any time by order of the Director of Public Safety or the Board of Health.

President A. A. Hirst was most bitter in his opposition to the resolution and declared that the notorious carelessness of medical students would spread contagion through the city. Dr. Walk and Dr. Lee favored the resolution for, as the latter justly said, how can a medical graduate be expected to recognize smallpox, for instance, when he has never had the opportunity of seeing a case? Action was deferred, but it seems probable that the resolution will be passed, especially as Dr. Welch, resident physician of the Hospital, has expressed his willingness to aid by giving ward instruction.

The total number of deaths occurring in Philadelphia during the week ending December 10th, as reported at the health office, was 436, of which 114 occurred in children under five years of age. The total number of new cases of contagious diseases was 228, reported as follows: Diphtheria, 94 cases with 17 deaths; scarlet fever, 22 cases with no deaths; typhoid fever, 112 cases with 7 deaths.

MEDICAL MATTERS IN CHICAGO.

MUSICAL HEART MURMURS—DIETETIC MANAGEMENT OF DIABETES—CASE OF DR. GUIDONE—THE ILLINOIS DRAINAGE CANAL FROM A SANITARY STANDPOINT—VITAL STATISTICS—SYMPOSIUM ON GONORRHEA.

CHICAGO, DECEMBER 12, 1898.

AT a meeting of the Chicago Society for Internal Medicine, held November 22nd, Dr. Henry F. Lewis read a paper on "Musical Heart Murmurs." He reported a case of mitral stenosis characterized by a musical murmur heard about the apex and at the end of the diastole. Musical murmurs heard over some parts of the heart's area, in various abnormal cardiac conditions, are not uncommon phenomena. According to Eichhorst, a musical bruit may be caused by a congenital aberrant cord running from the ventricle to the aortic wall. Huchard maintains that aortic regurgitation due to arteriosclerosis is more commonly accompanied by musical, rough or whistling murmurs than is that lesion due to other causes. While musical sounds are oftenest heard in the aortic region and are due to a lesion of the corresponding valve, yet sometimes mitral disease may be the causative factor. In the second case the musical murmur was heard with diastole over the right carotid as far up as the angle of the jaw, and for a short distance along the course of the right subclavian.

DR. CHARLES W. PURDY read a paper on "The Principles of the Dietetic Management of Diabetes Mellitus." He dwelt upon the general features of the disease and its amenability to treatment in the aged and in the young. He then spoke of the caloric value of the most suitable

foods in diabetes, the use of meat and the failure of the absolute meat diet. He pointed out the use of fat and its high potential value as a nutrient and force generator. The range of use of the carbohydrates was dwelt upon at length. Diabetes after middle life is one of the most manageable diseases with which the physician has to do, if he only has entire control of the patient. Reference is made especially to primary cases of the disease in people over fifty years of age, who have not already been neglected to the extent that the disease has made serious inroads upon the strength and upon the body weight of the patient. The diet of diabetic patients should be so ordered as to maintain, and, if possible, increase the body weight and strength of the patient, as these are the first to be undermined by the disease. In order to compass these primary objects a systematic series of frequently recorded observations must be made of the quantity and quality of the food actually ingested; of the quantity and quality of the waste excreted, especially by the kidneys, and of the actual body weight. By these means only it is possible to detect those disturbances of the metabolism caused by the disease and to refer directly to their cause. There exist among diabetic patients the greatest differences in individual capacity for utilizing the carbohydrates. Some can take and utilize comparatively large amounts; others very much smaller amounts; while a few cannot take carbohydrates in the smallest quantity without their immediate escape by the urine in the form of sugar. Not only this, but also very wide oscillations of the tolerance for carbohydrates occur in the same patients at different, and sometimes, very briefly separated periods.

Recently a Dr. R. F. Guidone was charged with practising medicine in Illinois without a license and was acquitted. The State Board of Health will appeal the case and this gentleman will be prosecuted if he attempts to practise further. The Illinois State Board of Health recognizes no foreign diplomas as a basis upon which to issue a certificate to practise medicine and surgery in Illinois. More than 50 per cent. of the degrees purporting to be issued by foreign universities which have been presented to the Board during the last two years have been found to be fraudulent.

With a view to protecting the taxpayers of Illinois against unwarranted claims for damages growing out of the operation of the drainage canal, Commissioner of Health Reynolds has addressed an important communication to the drainage board. Believing that the waters of the Illinois and Mississippi will not be polluted by the flow of the canal, he urges the necessity of preparing evidence at once, showing the present sanitary condition of the streams. A systematic and thorough official test is advised for the purpose of forestalling claims which are certain to arise after the canal has been opened.

The subject is one to which Commissioner Reynolds has given his personal attention for years. From tests of the water, made at various points along the route of the future flow of the drainage canal, he is satisfied that the water purifies itself by reason of natural conditions, and he is convinced that St. Louis, Peoria and the various towns touched by the line of the sanitary outlet for Chicago will not suffer by reason of a pollution of the water. To establish this fact he calls attention to the importance of official records showing the quality of the water at all of these points before and after the sewage of Chicago has been turned into the channel. Without this evidence, assuming Dr. Reynolds is correct in his theory, the sanitary district is threatened with an inestimable financial drain by reason of damage suits based upon the pollution of the water between Chicago and the Mississippi. Such examinations have been made from time to time since 1869—the most important, in point of number, being those instituted by the late Dr. John H. Rauch in 1866-89, made by Professor J. H. Long and collated by Dr. F. W. Reilly. While these examinations demonstrated the effective decomposition of sewage matters, and consequent purification of the stream in a flow of less than fifty miles—that is, between Bridgeport and Channahon—they are defective scientifically, in that they were confined solely to the chemic determinations, and in the present developed state of water analysis and examination, when water bacteriology is deemed essential, they would probably have little weight. This defect was, in part, remedied by the work done as late as September, 1894, by Dr. Adolph Gehrmann of the city department laboratory, who made a special bacteriologic study of certain organisms in the water between the south branch of the Chicago River and a point a few miles below Peoria. But this work was confined to the bacterial examinations and was not supplemented by simultaneous chemic analysis. Both are essential. If the suggestion be acted upon Dr. Reynolds will take general charge and arrange the details of the collection of samples, the points whence these shall be obtained, the technic to be employed in the examinations, the data to be included —meteorologic, topographic, demographic, etc.

From a sanitary point of view the people will watch with great interest the progress made in the construction of the drainage canal from the inception of the plan. It is an open question now whether the sewage of Chicago for all time can be disposed of by dilution as contemplated in the canal plan. If it cannot, eventually evaporation must be substituted, or at least, added. The existence of the drainage system will make that plan easier in any event, and the money spent in the canal will not have been wasted. But that has nothing to do with the question at hand. The operation of the drainage canal will be successful from a sanitary standpoint, both for the sanitary district of Chicago and for the country below. There is no doubt that the diluted flow in the canal will purify itself through the action of the air and by precipitation. An analysis of samples of water taken from the Illinois, Mississippi and other streams into which sewage empties confirms this belief.

There was an increase of 38 in the number of deaths from all causes during the week ending November 25th over the total of the previous week and an increase of 83 over the total of the corresponding week last year. This increase is chiefly in deaths from cancer, diphtheria, and nervous diseases. The number of deaths from cancer, 25, is the

highest ever recorded in any one week in Chicago. In his second annual report, that for 1894, Health Commissioner Reynolds showed that the mortality from this disease had increased 812 per cent. in the forty-four years between the ten-year periods, 1851–60 and 1885–94, and then pointed out that this enormous increase, the incurability of the disease in almost all its forms, and the increasing evidence of its infectious character strongly indicated the need of preventive measures, such as disinfection of dressings, clothing, etc., of cancerous patients during life and of premises after death to as full an extent as in the case of consumptive patients. Four hundred and sixty births were reported, 244 being of boys and 216 of girls.

At a meeting of the Chicago Medical Society, held November 30th, a symposium of papers was presented on "Gonorrhea." DR. F. KREISSL spoke of gonorrhea in the adult male, and pointed out as the cause of failure in dealing with the disease superficial diagnosis, incorrect conception of the gonorrheal process, improper selection of the remedies, and the almost universal tendency to start in with an effective treatment too late and to discontinue it too soon, and last, but not least, the lack of individualizing cases. Silver salts still rank very high in the treatment of this malady, and their value in destroying the vitality of the gonococcus is being more and more appreciated. DR. T. J. WATKINS dwelt upon gonorrhea in the female adult. DR. I. A. ABT discussed the subject of gonorrhea in children, saying that gonorrheal infection of children manifests itself primarily as a vulvovaginitis, a urethritis in the male child, a purulent ophthalmia, stomatitis, or rhinitis of the newborn. The disease occurs in children from one to twelve years old, although it is most frequent in children under six years of age. The vulva and urethra are most often attacked primarily; the vagina, if involved, becomes so secondarily. The gonorrheal virus may be conveyed through sponges, towels, bed linen, by manipulation of the parts with unclean fingers, fever thermometers, or the contagion may in rare cases be conveyed by criminal assaults on little girls. The prognosis in little girls is more favorable than in adults. He reported two cases as having come under his observation; one in a boy, aged two years and three months; the other in a patient nine years of age. DR. D. N. EISENDRATH read a paper on the pathology of gonorrhea and treatment of some surgical complications. DR. BERTRAM W. SIPPY dwelt upon gonorrhea from the standpoint of internal medicine. As etiologic factors he considered (1) the presence of the gonococcus; (2) the action of gonotoxins produced either at the site of the inflammation, or possibly conveyed by the blood to the part from the seat of primary infection; (3) secondary infection with various micro-organisms; (4) mixed infection. Arthritis occurs as a metastatic complication of gonorrhea in from 2½ to 3 per cent. of all cases. Endocarditis complicates gonorrheal processes much more rarely than arthritis. The left heart is more frequently affected. Diseases of the brain, spinal cord, meninges, cranial and peripheral nerves have been reported on good authority, in which gonorrhea was regarded as the etiologic factor. Functional disease of the nervous system is much more common in gonorrheal cases. There is nothing specific in the symptomatology of nervous disease complicating gonorrhea. A relatively large number of patients with myelomeningitis have recovered. Bacteriologic research has been attempted a few times, but thus far the gonococcus has not been found.

OUR LONDON LETTER.

[From Our Special Correspondent.]

A RARE CASE OF SARCOMA OF THE HEART AND KIDNEY—EMBOLISM OF THE COMMON ILIAC ARTERY AND VEIN, SPLEEN AND KIDNEYS IN TYPHOID FEVER—INCREASE OF TABES MESENTERICA IN CHILDREN DUE TO MILK—A STENOGRAPHIC MEDICAL JOURNAL—OLD MORTALITY REPORTS.

LONDON, December 5, 1898.

AT a recent meeting of the Pathological Society a large number of specimens was presented and reported upon, but only a few were of unusual interest. Among them was a sarcoma of the heart, presented by DR. H. LISTER. The patient was a young girl who was brought into the hospital complaining of pain and swelling in the abdomen. A tumor in the right lumbar region was promptly discovered and also a well-marked heart bruit and general pulmonary dulness. The latter rapidly progressed to congestion and the patient died in about two-weeks' time. At autopsy a rounded fleshy growth about the size of a hickory-nut was found projecting into the cavity of the right auricle and the right kidney was changed into a pulpy, dark-red mass, as large as a child's head. Both tumors upon microscopic examination were clearly sarcoma of the small, round-cell type, sections being exhibited. The interesting features of the case were its great rarity, only some fifteen cases of primary sarcoma of the heart being on record, and the extremely rapid growth of the tumors which produced death within a month from the time of the first appearance of any noticeable symptoms.

DR. WILLIAM HUNTER showed specimens of complete embolic obstruction of the common iliac artery and of the corresponding vein upon the right side after typhoid fever. The leg became completely gangrenous up to the upper third of the thigh, but as an interesting confirmation of the belief that the septic processes of even gangrene are caused by infection from without, on being thoroughly asepticized and wrapped in salicylated wool and sublimate gauze it dried up and mummified without giving rise to any septicemic symptoms whatever. The patient, a boy aged fifteen years, lived three weeks and then succumbed to further embolization of the spleen and kidneys, and finally thrombosis of the apex of the left ventricle, all of which viscera were exhibited. Truly, the limit to the possible sequelæ of typhoid does not seem to have been reached yet. Several similar cases were reported by Drs. Boyd and Hawkins.

A specimen of primary carcinoma of the gall-bladder without a calculus was shown by PROFESSOR ROSE BRADFORD, and a similar condition with a large calculus firmly embedded in the grasp of the growth by Dr. William

Hunter which brought forth a discussion of the mooted question of the causal relations between calculus and cancer. The balance of opinion inclined to the coincidence view.

DR. HADLEY presented a specimen of that rare condition, primary carcinoma of the pleura with secondary deposits in the kidney, liver, and heart.

At Mr. Jonathan Hutchinson's weekly demonstration at his clinical museum last week two rare cases were shown, one of rapidly growing neuroma upon the lower trunks of the brachial plexus in a woman aged seventy years. The tumor had been noticed only one year, was of the size of a walnut, and caused both night-pain and sharp tingling sensations in the forearm and fingers, especially on the radial side. There were two smaller tumors just below it upon the nerve-trunks. On account of its rapid growth and tendency to become multiple Mr. Hutchinson advised its removal.

The other case was a flat, painful, contracting induration of the skin of the axilla in a man aged eighty-six, which strongly suggested to the lecturer scirrhus of the axillary sebaceous glands. This, though rare, we have little reason to be surprised at on embryologic grounds, as the highly susceptible mamma is but a specialized cluster of these large sebaceous glands. The patient's back and chest were also covered with the yellow plaques of tinea versicolor, and Mr. Hutchinson called attention to the fact that there is a regular succession of tineæ corresponding to the different ages of life. In childhood tinea capitis or tonsurans flourishes, but dies out about puberty or early adult life, tinea barbi attacks the beard, scalp and eyebrows, but loses its power of lodgment by middle life. In middle life man is susceptible only to tinea versicolor, and in old age, as a rule, he becomes immune even to this, the present case being a rare exception.

In the second Harveian Lecture on "Tuberculosis" week before last SIR RICHARD THORNE THORNE took up the question of dissemination through milk. He adduced the interesting fact that although the deaths from pulmonary tuberculosis in adults have decreased nearly thirty per cent. during the last twenty years, yet the deaths from intestinal tuberculosis (tabes mesenterica) in children under one year have increased nearly twenty per cent., so that they account for nearly twenty per cent. of all deaths under this age, a change which he could not help associating with the immense and otherwise infinitely beneficial increase in the use of milk as the main food for children. Bacteriologic examination of numerous samples of milk taken from the stalls in several English towns had revealed tubercle bacilli in from four to eight per cent. of them. He urged vigorous and frequent veterinary inspection of all dairy cattle but thought the tuberculin-test impracticable on account of the enormous expense of killing every animal that reacted, and also because it would disqualify nearly one-third of the cows at present in our dairies and thus cause a serious shortage in the milk-supply. The last consideration strikes us as being rather a singular reason. His own remedy is the condemnation of every animal showing signs of advanced tuberculosis of any organ or of disease of the udder.

A unique curio of medical literature is the little London *Photographic Record of Clinical Teaching and Medical Science*, edited by the Society of Medical Stenographers, of which Sir William Gowers is the leading light. Into a thin, small pamphlet of fifteen pages about six inches by four, are compressed four to six original articles and case reports, several editorials, and a column or two of news items. It is printed in pure Pitman shorthand, and for compactness the contrast between it and the average medical journal is like that between a pound of sugar and a gram of saccharin. Its neatness, lightness, and economy of print and space make us long for the day when nothing but shorthand as a means of literary expression will be taught in our schools and all our literature can be reduced to this compact and beautiful form.

A correspondent of *Guy's Hospital Journal* has unearthed an ancient copy of the Bills of Mortality for London of a week in October, 1714. Some of the causes assigned are delicious and in their frank agnosticism contrast most favorably with our modern "heart-failures," "asphyxias," and "malnutritions." Thus, "griping in the guts" is credited with eight deaths, "stoppage in the stomach" with ten, and the climax is reached by three which were caused by "suddenly." A startling commentary upon certain recent legislation are the deaths from smallpox, which were 73 in one week, or fifteen per cent of the whole list. A fascinating but mysterious finding is "rising of the lights," a disease now almost extinct, unless it may be in some remote rural districts of the Middle West of the United States, where we have heard a patient described as "coughin' fit to raise her lites an' liver."

TRANSACTIONS OF FOREIGN SOCIETIES.

French.

TOXICITY OF APPENDICITIS—SUCCESSFUL RESECTION OF THE STOMACH—HOW FAR IS THE SPHINCTER ANI INDEPENDENT OF ITS NERVES?—DIFFICULTIES OF JEJUNOSTOMY—TO REMOVE FOREIGN BODIES FROM THE NOSE—SALINE SOLUTIONS IN INFECTIONS—NAUSEA AS A PREMONITORY SYMPTOM OF NEPHRITIS—BALDNESS CAUSED BY A NEW DRUG—STERILIZED MILK AND GASTRO-ENTERITIS—TWELFTH CONGRESS OF SURGERY.

AT the Academy of Medicine, November 8th, DIUELAFOY spoke of appendicitis as an affection not only infectious but toxic as well. Urobilinuria and albuminuria are by no means uncommon symptoms, and in grave cases there may be cerebral and bulbar symptoms of a typhoidal character. The icterus and the cerebral symptoms develop in general sooner than similar symptoms of an infectious origin, appearing in the earlier days of the disease, and often in the case of jaundice, before there is fever.

At the Session of November 15th, LE DENTU substantiated the claim for a toxicity of appendicitis. A little girl upon whom he had operated for suppurative appendicitis, developed two days later hydrencephalic cries, and died forty-eight hours later in collapse. The reason assigned was that of secondary metastatic meningitis. He had seen

icterus only in cases of chronic appendicitis. One patient who had suffered for months with gastro-intestinal symptoms and icterus was relieved of all his symptoms including the icterus by the removal of his appendix.

Perier presented a woman from whom a year previously he had removed the central portion of the stomach and the corresponding part of the transverse mesocolon for carcinoma. The parts of the stomach were united by a double row of sutures, and covered with omentum. Recovery was perfect, the patient had gained twenty-five pounds in weight, and there was as yet no sign of recurrence. The result was most encouraging. The speaker called attention to the importance of an empty intestine in operations of this character. This is easy to obtain as far as the small intestine is concerned, but the large intestine will often be found distended with fecal matter, especially if the patient has been upon a milk diet. If such a condition is found at laparotomy a fatal issue may sometimes be avoided by crowding the fecal matter through the colon into the sigmoid flexure.

At the Academy of Sciences, November 7th, Arloing and Chantre told of the results of experiments upon the sphincter ani of dogs. After the complete division of the nerves which supply the sphincter ani, the elasticity of this muscle will prevent incontinence of feces and urine, and its physiologic and anatomic properties are preserved at least a year after bilateral nerve section, while unilateral division of the nerves has no apparent effect upon the sphincter, either upon its structure or function.

At the Society of Surgery, November 9th, Terrier described a jejunostomy for cancer of the stomach so extensive that gastro-enterostomy was impossible. A loop of intestine was fixed in the abdominal wall, and opened fifteen days later. Owing to the small caliber of the intestine and the force of peristaltic effort, it was difficult to introduce nourishment, and still more difficult to prevent its being ejected.

Le Dentu performed jejunostomy under similar gastric conditions but the patient speedily died.

Peyrot performed the operation twice. One patient died almost immediately. The other lived fifteen days only, but during this time he was fed without difficulty through the intestinal fistula.

Guinard had experience with a fistula of the small intestine due to strangulated hernia. He found it impossible to introduce nourishment, except in the smallest quantities.

At the meeting of November 16th, Felizet told of the success which he had in the removal of foreign bodies from a child's nose, by the simple maneuver of forcing air with a powder blower into the free nostril. This expedient succeeded in 26 out of 31 cases, in forcing the foreign body out of the nostril in which it had become lodged. In the other instances forceps were used.

At the Therapeutic Society, November 9th, Bolognesi read a paper upon "Saline Solutions in the Treatment of Infections," in which he admitted the value of intravenous saline injections but gave it as his opinion that this form of administration should be confined to grave obstetrical and surgical cases. The washing of the blood, which it was claimed would result from their use, and which would free the body of poisons in infections, is not thus accomplished. In infections or intoxications, saline solutions should be administered either subcutaneously in moderate doses, 100, 150, or even 500 c.cm., (3 to 16 oz.), the effect upon the heart being carefully noted, or the solutions should be administered by the rectum. Such treatment is beneficial in conditions of hypotension and collapse.

Dalche agreed that saline injections have no antitoxic value. He had seen good results follow their use in poisoning from coal-gas. Recently he had injected subcutaneously 800 c.cm. (26 oz.) for suffocation by carbon monoxid. The condition of the patient rapidly improved.

Mathieu has noted that a persistent nausea may be the forerunner of insidious nephritis, appearing with or without headache some time before albumin can be found in the urine. These gastric symptoms mislead the physician into supposing that he has to do with a disorder of the stomach, while in reality they are the signs of commencing uremia. He had observed this in five or six patients. In order to suppress the alimentary intoxication, and to assure intestinal antisepsis, the patient should be put upon a milk diet, and the bowels should be kept open with scammony or laxative waters, or large intestinal injections may be administered. If the stomach is intolerant of food the patient should be kept upon a fluid diet, or even deprived of all nourishment for a time. By these means it is usually possible to obtain an improvement lasting for a considerable period.

Jeanselma warned the Society for Dermatology and Syphilography, November 10th, against the use of the acetate of thallium, a remedy recently introduced into therapeutics. This drug may cause a rapid and complete falling out of the hair. A woman took in three days about four grains of this remedy. Two weeks later almost all of her hairs had dropped out, the few remaining yielding to the least traction. One month later there was a scanty growth of some of the broken hairs, but in three months baldness was still so nearly complete that there was little hope that the hair would again grow. This instance may serve as a warning against the careless use of new remedies.

At the Medical Society of the Hospitals, November 18th, Lesage described some facts which he had established in connection with an epidemic of gastro-enteritis which had raged in Paris, in August and September last. In the first place infants fed upon sterilized milk were attacked just as frequently as those fed upon raw milk. Furthermore, there was no difference in the course of the disease, or in its symptoms in the two classes of infants. All the injections made subcutaneously into guinea-pigs were without result when the filtered intestinal contents were employed, thus showing that there was no toxin in the intestine. If the epithelial lining of the intestine was macerated and the fluid from it injected, it was in a certain number of cases found to be highly toxic. The bacteria found in the intestine aside from the colon bacillus, were inconstant and varied in different seasons, and also

in different individuals in the same epidemic. It is hard to say just what the exciting cause of such an epidemic really is. The speaker thought that a reason might be found in the prolonged and excessive heat of the latter part of the summer. Such a heated term might increase the virulence of the bacteria normally found in the intestine, especially the bacillus coli, until it was capable of setting up a gastro-enteritis.

The Twelfth Congress of Surgery was held in Paris, October 17th to 22d.[1] FORGUE described an "Intramediastinal Esophagotomy for a Foreign Body in the Thoracic Portion of the Esophagus." A child eight years old had swallowed a large coin. Numerous attempts to dislodge it were made by several different physicians. The radiographs showed it to be situated at the level of the fourth intercostal space, plainly to the right of the vertebral column. It was, therefore, decided to operate upon the right side, in spite of the difficulties of that route. A vertical incision, 14 cm. (5.5 in.) in length, was made between the right scapula and the spinal column. The angles of the ribs were exposed. Sections were removed from the fourth, fifth, and sixth ribs, 5 cm. (2 in.) in length. Through the window thus made the fingers could be introduced, and the separation of the parietal pleura accomplished. When the fingers reached the lateral flank of the vertebræ, the coin was easily felt. The pleura was stripped from the vertebral column without difficulty, but when attempts were made to separate the pleura and esophagus, they failed because the esophagus was lifted with the pleura, away from the vertebræ. The coin could no longer be felt, and as the condition of the child did not admit of longer operative interference, the wound was tamponed. Twelve days later it was decided to make another effort to get at the coin, but before doing so a Graefe basket was passed into the esophagus, and this extracted the coin without difficulty.

In considering the relative advantages of right or left thoracotomy in accidents of this character, it is necessary to remember that foreign bodies in this part of the esophagus almost always lodge opposite the fifth, sixth, or seventh dorsal vertebra. The esophagus will have to be uncovered by touch and not by sight, and at a depth of three or four inches. On the right side the pleura begins at the sixth vertebra to invaginate itself between the esophagus and the spine and this invagination grows deeper till the esophagus passes into the stomach at the tenth vertebra. On the left side there is no such invagination, as the aorta intervenes, and in spite of the fact that this vessel has to be passed over the operation upon the left side is thought by Forgue to be more easily carried out. This is also the opinion of some of the anatomists who have studied the subject, while others have held the opposite view.

REDARD considered that radiographs are of the greatest assistance in the treatment of Pott's disease as they show the extent of the lesions, the presence of cold abscesses, and the exact position of the bones. They also show the progress which is made toward recovery under the treatment adopted. In short they give in the living most of the information which one is able to obtain after death by anatomopathologic investigations. In the treatment of scolioses radiography is equally valuable.

FROEHLICH, who had opportunity to study twenty-six cases of Pott's disease in nursing children, found that the lesions were situated in the first and second lumbar vertebræ in twenty-two of the twenty-six infants. In only four, was there an abscess. The prognosis is better than in older children, only four of these having died. Persistence of the symptoms is also an exception. The disease had a duration of between one and two years. In its early stages the trouble is not easy to recognize. When paraplegia arises, it may lead one to think of infantile paralysis, but in Pott's disease there is never a reaction of degeneration, and the paralysis, which is incomplete, is confined to the lower extremities. There is rigidity of the spinal column. In rachitis, inability to move the limbs is due to the pain in the bones on pressure, and this will serve to distinguish it from Pott's disease. If Pott's disease begins with a boss, it may be very hard to tell it from a kyphosis occurring in rickets, though in the latter the kyphosis is usually dorsolumbar, and there will be signs of rickets elsewhere in the body. For infants under one year, the best treatment consists in fixing them upon a board in an attitude of marked lordosis. For those over one year a plaster jacket may be applied in such a manner as to permit of its removal. Of these 26 patients, 4 died, 10 were still under treatment at the time of report, and 12 were cured.

ROUX reported upon the past two years in gastro-intestinal surgery. He spoke of the hopeful sign that patients, whether from a physician or not, come much earlier than formerly to the surgeon. In consequence there are fewer hopeless cases, and instead of having to reject 36 per cent. of applicants as beyond the help of surgery, he had only 4 such patients in the two years referred to. Pylorectomy for cancer was performed 12 times with 3 deaths (25 per cent.). Gastro-enterostomy by the Y-method was performed 31 times with 3 deaths (10 per cent.). Posterior Y-shaped gastro-enterostomy with three planes of suture is not a dangerous operation. In 24 non-malignant cases, it was performed without a death.

GALLET performs gastro-enterostomy in the following rapid manner: A loop of the jejunum is selected and stitched to the stomach along one edge. It is then opened and the halves of a Murphy button are passed on clamps into the ascending and descending portions of the loop of jejunum, and pressed together through its walls. This procedure takes scarcely two minutes, and avoids the stoppage of bile in the ascending part of the loop. The gastro-enterostomy is then completed, and afterward the ascending part of the loop of jejunum is divided between ligatures and each cut end invaginated and sutured. The whole procedure should not occupy more than thirty minutes.

JORDAN said that Murphy's buttons are employed in Czerny's clinic as frequently as possible, as they reduce the time of operation by about one-half. It is considered dangerous to use the button in connection with the

[1] The first part of the proceedings was reported in the MEDICAL NEWS for December 3d, p. 736.

large intestine. Gastro-enterostomy had been practised 83 times, the posterior method being employed in all but 5 of these cases. The mortality was 12.5 per cent.

TUFFIER'S mortality after pylorectomy was thirty-three per cent. For gastro-enterostomy he preferred the posterior method whenever it was possible to bring out the stomach.

MONPROFIT performed gastro-enterostomy nineteen times, and had only two deaths (ten-per-cent. mortality) as a result of operation. He favored the posterior method of Von Hacker.

REVERDIN read a paper upon "The Surgical Treatment of Goiter." In cases with moderate interference with breathing anesthetics may be used as in other operations, but in retrosternal cases and in all cases in which the breathing is much hampered, general anesthesia should be avoided and the operation done by means of Schleich's cocain anesthesia, and with as little of that as possible. Statistics were given of 6103 operations for goiter, with a total mortality of 2.88 per cent. If only uncomplicated cases are considered, the mortality is almost nil. Extra-glandular enucleation has a mortality of 0.78 per cent.; partial extirpation, one of 3.5 per cent., and resection according to Mikulicz, 6.7 per cent. Total removal of the gland has a mortality of 18.9 per cent. and ought never to be performed. In after-effects enucleation is far superior to any other operation, as may be naturally supposed since it does not sacrifice healthy gland-tissue. It is the operation of choice and should be performed whenever possible.

SOCIN never uses ether in operations upon the trachea and larynx. When operating upon goiter he uses cocain when possible; otherwise chloroform. He attributes the deaths after the operation to the use of chloroform in many instances. In his last 200 operations he had only one death, from hypostatic pneumonia. One hundred and seventeen of these operations were enucleations.

ROUX had operated 526 times, using cocain whenever possible, as the operation is less bloody, more easily performed, and less dangerous from the fact that the patient shows at once when the trachea is drawn upon or injured, and thus more than once tracheotomy has been avoided. It is interesting to note, however, that pulmonary congestion was just as common after operations done with cocain as when a general anesthetic was used. Of the 235 patients operated upon since a previous report, only three died, giving a mortality of 1.27 per cent.

GIRARD reported 545 operations and only six deaths, a mortality of 1.1 per cent.

SCHWARTZ has operated upon more than one hundred patients for enlarged crural veins, either uncomplicated or in the presence of ulcers, phlebitis, etc. Only one patient was lost, and she apparently died of heart trouble. No pulmonary embolism could be found. It has been demonstrated that varicose ulcers readily heal after the ligation of the saphenous vein. Schwartz carries the operation further, and advocates the removal of phlebitic varicosities, first tying the veins above, to prevent embolism.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Regular Meeting, Held November 28, 1898.

THE new President, DR. S. O. VAN DER POEL, delivered his inaugural address, taking for his subject

MEDICAL ASPECTS OF LIFE INSURANCE.

He said, in part:

Life insurance is a matter of interest to a great many members of the medical profession and hence requires no apology in forming the subject of an address before a general medical society. While not originally an American institution, it has in this last decade or two made wonderful extension among us. American enterprise took the insurance system that the English had made and kept up for a few select lives and made of it a thing for the millions. With this extension large numbers of the medical profession were necessarily drawn into closer relations with it.

The insurance examiner, however, approaches a case from a very different point of view from that of the practitioner. It is prognosis, not diagnosis, that he wishes to get the material for. It is a mistake, that the novice in the insurance line often makes, to approach a case with the habit of mind that refers everything to diagnosis. Prognosis is a much more difficult problem; its more exact study in recent years has allowed of the acceptance by insurance companies in England of risks on damaged or "substandard" lives. Muirhead of Edinburg has especially distinguished himself in showing the scientific bases on which the expectancy of life in these cases can be reckoned, in order to assure the company against loss when a series of risks are taken. People suffering from valvular heart lesions, from gout, asthma and the like, can under certain restrictions and a correspondingly increased premium now take out English policies. Such risks have been absolutely refused so far in America, except for short terms on the endowment plan. Recently, however, Dr. Oscar H. Rogers of New York, after a most careful collection of statistical material in the matter (as yet unpublished), has demonstrated that the benefits of life insurance may be extended to these substandard lives without loss to the companies. Insurance companies have been too much blamed in the past for refusing to assume risks on applicants who were not up to the standard, but their position is an extremely difficult one. While it may seem that at thirty a man with cyclical albuminuria is in as good health, apparently, as another without it, who can give any assurance that it will be so twenty years later? The increased amount of observation required for the settlement of difficult problems of prognosis on practical scientific bases will undoubtedly redound to the good of general medicine. Just as the adoption of life insurance by Americans has led to its present wonderful development, so the adoption of this new feature will undoubtedly result in extension of life insurance along new lines.

DR. W. H. THOMSON then read a paper on

CUBAN MALARIAL FEVER,

which will be found on page 777 of this issue of the MEDICAL NEWS.

DR. ROBERT L. WATKINS followed with a short paper, fully illustrated by stereopticon views, on

THE CUBAN FEVER PLASMODIUM,

an abstract of which appears on page 781.

In the discussion which followed these papers DR. WICKES WASHBURN asked leave to state the condition just after being landed from the transports of some of the patients who had later been under treatment by Dr. Thomson.

A number of them were under his care at Montauk Point. A sample of the conditions in which they were received at the camp would be about as follows: One afternoon it was announced by a mounted officer who had ridden up in hot haste, that a number of sick soldiers were on their way to the hospital. Before any arrangements could be made for their reception they arrived. About seventy-five in number, they had been packed into stages, and for lack of room had been persuaded into making an effort to sit up. The day was terribly hot and sultry, the roads dusty and uncomfortable, the ride long, at least for sick men. One by one weakness had overcome them and they had sunk helpless upon the bottom of the stages. No one was able to help his neighbor because of his own weakness. Not a dozen men out of seventy-five had not sunk into collapse. Despite their weakened condition and the severity of their infection, however, all of them except one eventually recovered. This incident gives a good illustration of the terribly unfavorable conditions the medical men at the camp, but very limited in number at that time, had to deal with.

Temperatures in the cases, probably owing to the great prostration among the men, ran very high. Above 104° F. was not unusual, and 105° F. and even higher was frequently seen. Despite this high temperature, quinin acted, as a rule, very promptly and effectively. Fifteen grains administered to men having almost a continuous temperature of 104° F. brought it by the next morning down to 100° F., and, repeated soon, led to normal temperatures. Relapses, however, were not infrequent. This was not surprising, as most of the cases were complicated by other affections. Dysentery or slighter diarrheic conditions, catarrhal jaundice, dyspeptic troubles, and, finally, that extremely important ailment in the young soldier, homesickness, all acted as depressing agents which lowered very materially resistive vitality and delayed that recuperative reaction that one expects to find in the young.

It was difficult, too, to have the men take their medicines after symptoms had subsided, so that he was not surprised to hear of the men later sinking in the streets or being taken with the disease at their homes after their discharge from the hospital. Besides quinin in the ordinary way Dr. Washburn had tried the bimuriate of quinin and urea, by subcutaneous injection, and had had excellent results from it. It was especially useful in the cases complicated by diarrhea, in which the irritant effect of the quinin on the already irritated intestines contraindicated its administration by the mouth, and in which, besides, the giving of it in this way was unsatisfactory because of the uncertainty of how much would be absorbed.

DR. J. F. CHMELICEK said that his experience with more than 600 cases of Cuban malarial fever enabled him to confirm Dr. Thomson's opinion as to the advisability of administering quinin with some one of the spices, ginger, pepper, or capsicum. He has especially found that small doses of the essential oil of pepper have the effect of making the quinin less irritating to the stomach and of hastening its absorption, as well as of rendering its absorption more complete. With regard to perforation in typhoid fever, his experience is also confirmatory of that of Dr. Thomson. It is in the ambulatory cases, when the patients keep on their feet well into the second week of the fever, or even longer, that perforation occurs most frequently.

In conclusion, Dr. Thomson said that the main thing he wished to insist on as the result of his experience with the estivo-autumnal type of malaria, as he saw it at the hospital this fall, is that it frequently does not yield to quinin, and that some other active remedial agent needs to be combined with it. In all cases in which the disease failed to present definite paroxysms quinin alone was ineffective. The remembrance of this fact makes the way clearer for the clinical therapeutist.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Proceedings of the Eleventh Annual Meeting, Held at Memphis, Tenn., December 6, 7, and 8, 1898.

FIRST DAY—MORNING SESSION.

THE Association met at the Gayoso Hotel under the presidency of DR. RICHARD DOUGLAS of Nashville, Tenn.

Prayer was offered by BISHOP GAILOR.

DR. ALEXANDER ERSKINE of Memphis delivered an Address of Welcome on behalf of the local profession, which was responded to by PRESIDENT DOUGLAS.

After the disposal of routine business, the scientific session was opened with a paper by DR. WILLIAM E. PARKER of New Orleans, La., entitled

GUNSHOT WOUNDS.

He described the hospital conditions in Cuba and the wounds seen by him made by the modern bullet. He spoke of some experiments made under the direction of Major and Surgeon L. A. LaGarde of the regular army, as to the relative penetrating powers of the Mauser, Krag-Jörgensen, and Springfield rifles. With ammunition of the years 1896 and 1897 the Mauser, fired at a distance of three feet from the muzzle into seasoned yellow-pine posts, would penetrate thirty-four plus inches. With ammunition of 1895 it would penetrate thirty-two plus inches; with ammunition of the past year, the Krag-Jörgensen, fired at the same distance, would penetrate twenty-four plus inches, and the Springfield would penetrate but five inches; yet many lodged Mausers were

found, and he was told by the Spanish chief-surgeon that but six lodged Krag-Jörgensens were found by them.

In speaking of wounds of special regions, he said that flesh wounds, as a rule, healed under one dressing. In the few cases that did not the sloughing was at the points of entrance and exit, and not along the whole track of the bullet. Explosive effects were not seen by any of the surgeons. He stated that he had hoped to present some statistics as to the wounds of the war, but they could not be had. Wounds of the brain did well. He had heard of at least five patients who were still alive and doing well. But one patient with a wound of the spinal cord was operated upon, and he was doing well. This patient had paralysis of both legs and of the bladder and rectum. Some spicules of bone had been removed from the cord. At the present time the patient has perfect use of the right leg and partial use of the left, and has perfect control of his bladder and rectum. He said that while he had not in any way modified his opinion that laparotomy should be done for abdominal wounds in civil life, that with the small modern bullet and lack of proper facilities this operation should not be attempted in the field unless there should be symptoms of hemorrhage. About fifty per cent. of these patients recovered without operation. Chest wounds did well, and caused but little trouble. When nerves were injured, nerve suture was not attempted on account of the rush of work, but he thought it should be attempted as soon as possible. None of the hospitals had a sufficiently large number of surgeons or hospital-corps men, but he spoke of the efficiency of those who were there.

DR. F. W. MCRAE of Atlanta, Ga., followed with a paper on

PENETRATING WOUNDS OF THE ABDOMEN, WITH REPORTS OF CASES.

At the outset, the essayist referred to a resolution passed unanimously by the Association at its Nashville meeting in 1896, to the effect that in all cases of penetrating wounds of the abdomen, it is the duty of the surgeon to make an exploratory incision so as to definitely determine whether the viscera have been injured or not. Since then a few able surgeons have dissented from this opinion. The propriety of surgical interference in cases of penetrating gunshot wounds of the abdomen will depend on one of three things: (1) The general condition of the patient; (2) dangerous internal hemorrhage; (3) wounds of the stomach or intestines large enough to permit extravasation.

Dr. McRae quoted from contributions to this subject by Senn, Nunez, Winslow, Budinger, Vaughan, Woolsey, Robson, Chaubel, Michaux, Klemm, etc., and said from the conflict of opinion and advice given by these and various other surgeons, one is at a loss to know just how to proceed in many cases. His own convictions, based on sixteen cases which he narrated, are positive. While he has the greatest admiration and respect for the surgical opinions of Senn, he should be recreant to his convictions were he to accept the proposition of non-interference laid down by Senn in his recent contributions to the subject. In most of the cases which have come under his observation where grave lesions of the abdominal viscera have existed, the symptoms of internal injury were practically *nil*, and the positive signs of grave damage almost entirely absent.

In conclusion, he reiterated his firm conviction that every case of penetrating wound of the abdomen, where there is a reasonable doubt as to injury of the abdominal viscera, should be subjected to at least an exploratory operation. This enables the surgeon to either be absolutely sure that no injury has been done to the viscera, or to repair, as far as possible, such injuries when they exist. The mortality following a simple exploratory operation *per se* is so small as not to weigh against the much greater mortality that necessarily follows the expectant plan of treatment. In the cases he had seen the general and local signs have been so misleading and enigmatical that prior to the operation a conclusion on his part as to internal conditions would have been entirely guess work.

THE PRACTICAL MANAGEMENT OF BULLET WOUNDS OF THE ABDOMINAL VISCERA.

This paper was read by DR. HORACE H. GRANT of Louisville, Ky. Observation and experience with operators coming frequently in contact with this lesion have determined that penetrating wounds of the abdomen demand laparotomy at the earliest possible moment after diagnosis and thorough inspection of the entire region endangered. It is established that not only is the mortality in untreated wounds of the abdomen almost one hundred per cent. where the intestines are perforated, and very high in wounds of the solid viscera, but it becomes less promising every advancing hour, until by the second day peritonitis sets in and destroys the hopefulness of the prospect. Within the past two years the speaker had operated in four cases. In each case the patient was seen early; in no instance later than four hours. In three resection of the intestine was necessary. Three of these patients recovered; the fourth died from septic peritonitis due to the escape of a large quantity of fecal matter before operation. Autopsy disclosed a perfect intestine.

These three papers were discussed together.

DR. W. L. ROBINSON of Danville, Va., said he has seen a good many cases of gunshot wounds of the abdomen, and nearly all of the patients died either with or without operation. Early operative interference might have saved some of them.

DR. G. S. BROWN of Birmingham said he knew of several cases of gunshot wounds of the abdomen that occurred in and around Birmingham, the patients recovering without operation. Personally, he had operated on five patients, one of whom recovered. In this case there was no perforation of the intestine. Undoubtedly diarrhea and starvation, mentioned by Dr. Parker in his paper, have something to do with the favorable results. The intestines are most liable to be perforated when full.

DR. WILLIS F. WESTMORELAND of Atlanta said the results of gunshot wounds of the abdomen on the battlefield should not be compared with those met with in civil life. It is not a question of operating, so far as fatal re-

sults are concerned, but the manner in which the operation is done.

DR. W. E. B. DAVIS of Birmingham thought that Dr. Parker's paper was not an argument against operative procedures for abdominal wounds. Surgeons on the battle-field do not have the same facilities for operating on penetrating wounds of the abdomen that they do in civil practice, and which are necessary for the proper care of cases. If a man sustains an injury to the intestine, if his abdomen is not opened death may be expected. In the case of twenty or more patients operated on by him and his brother, all died who were seen twenty-four hours after the injury. This is not an argument against operative interference, but against late operation. Statistics impress surgeons with the importance of early operation.

DR. GEORGE A. BAXTER of Chattanooga believes it is not necessary in many instances to open the abdomen in cases of gunshot wounds, and cited a number of cases of recovery without operative interference.

DR. JOHN T. WILSON of Sherman, Texas, advocated early operation in cases in which the surgeon is convinced that perforation has taken place. The character, technic, and rapidity of the operation are very important. In operating, the intestines should be exposed as little as possible.

DR. W. L. RODMAN of Louisville said that while he has pursued the practice of operating in penetrating gunshot wounds of the abdomen for the last ten years, after hearing the paper of Dr. Parker and reading the recent contributions of Senn and others, he wondered whether he as well as other surgeons may not have gone too far in operating in so many of these cases; at the same time, he does not wish to be understood as advising a masterly inactivity when the environments for operative interference are favorable.

DR. WESTMORELAND said that given a case of perforation of the intestines, particularly where there is extravasation of contents, instead of being masterly inactivity it is criminal inactivity for a surgeon not to operate.

DR. PARKER, in closing the discussion on his part, said that he had tried to make a clear distinction between the plan of treatment of gunshot wounds of the abdomen met with on the battle-field and those encountered in civil life. He is strongly opposed to laparotomy on the battle-field on account of the conditions that exist. In civil life, however, the thing to do in cases of gunshot wounds of the abdomen is to get in and out of the belly as soon as possible consistent with good work.

DR. MCRAE believes that a large proportion of the operations undertaken late for gunshot wounds of the abdomen will terminate fatally.

DR. GRANT stated that practically all patients operated on after twenty-four hours perish. It is impossible to diagnosticate perforation of the intestines with any degree of certainty. If a patient is seen within eight or ten hours after the receipt of a gunshot wound of the abdomen, under favorable surroundings, whether the bullet has penetrated the intestine or not, the skilful surgeon will not hesitate to make, at least, an exploratory operation, because it will not hurt the patient, but will probably save his life.

AFTERNOON SESSION.

DR. W. D. HAGGARD, JR., of Nashville, Tenn., read a paper, entitled

A PLEA FOR THE MORE CORRECT APPLICATION OF THE EMMET METHODS IN PLASTIC SURGERY.

The pioneer work of Sims was feelingly referred to. It is a unique circumstance in the annals of surgery that the instruments which made the feat of Emmet possible, and the fundamental principles of his success have remained unchanged. It is not so much the truth of homage to unprecedented genius, as the truth of the great principles he enunciated, and the perfection of his devices. The extension of the method of Sims in fistula to injuries of the adjacent soft parts was made by Emmet. The evolution and perfection of the operation on the cervix was traced. Dr. Haggard described the mechanics of the production of rectocele associated with the common transverse tear of the posterior vaginal wall involving the pelvic fascia, which is the essential pathology in this injury. The rational correction of this complex condition then would be not to sew the labia together, which is the popular procedure in one class of operations, nor to denude an arbitrary area of fanciful shape on the rectocele and bring the edges of the raw patch together, after the fashion of another class. It would rather be in the language of Emmet "to catch up the retracted pelvic fascia at such a point and in such a manner as to take in the slack, as it were, of the fascia throughout the pelvis." By this procedure the displaced posterior vaginal wall is certainly lifted up and drawn forward in contact with the vesicovaginal septum. As the steps of the operation advance the displaced anus is lifted upward and forward, the everted tissues at the vaginal outlet gradually rolled in and the separated levator ani muscles brought together. He accentuated the essential features in detail. The classical operation for the complex tear of the perineum is more amenable to pictorial description and he believes it more generally understood. He minutely depicted it.

THE TREATMENT OF COMPLETE RUPTURE OF THE PERINEUM BY DISSECTING OUT THE SPHINCTER MUSCLE AND ITS DIRECT UNION BY BURIED SUTURES.

DR. HOWARD A. KELLY of Baltimore, Md., read a paper on this subject, in which he said the results of the best methods of the treatment of complete tears of the perineum are not entirely satisfactory in a large percentage of cases. The control over liquid motions and flatus are, as a rule, not secured immediately, and it is usually necessary to encourage the patient by telling her that she "will have to learn to control the muscle in the course of time." Such a control, more or less perfect, is gained in the course of several months. This defect in our present procedures is due to a faulty approximation of the sphincter ends which lie buried in a pit, and are, therefore, difficult to bring into accurate, firm apposition by sutures embracing a considerable quantity of tissue surrounding the sphincter ends. Dr. Kelly proposes, therefore, the deliberate dissection and freeing of the sphincter

ends, drawing them out about one and one-half centimeters from the tissues, cutting off the scarred ends, and effecting a direct union of the freshened ends by two or three buried catgut sutures. He was led to do this operation by his experience in a case which had been operated upon six times with a result, which, judged by superficial appearances, was perfect, and yet the patient had no control over her bowel functions. He made a semilunar incision around the anterior periphery of the anus, and found the right sphincter end buried in scar tissue in the median line, while that of the left side was ectopic and attached out under the ischial tuberosity. The sphincter ends were united directly by buried catgut sutures, and the skin wound closed and union took place *per primam*. In addition to these buried catgut sutures a splinting suture of silkworm-gut is passed through the middle of the sphincter near the edges of the wound, and on up through the septum, splinting the ends together, and taking the tension off the catgut. He has since taken the hint given by this case and adopted a similar procedure in six cases of complete tear of the perineum due to confinement. Two additional patients were operated upon by Dr. W. W. Russell and one by Dr. Ramsay. In each instance there was a surprising difference between the new and older methods, noted at once in the earlier stages of the convalescence, and the patient was immediately conscious of perfect control of her functions. The bowels should never be locked up.

Great care must be taken not to leave any dead spaces in closing the remainder of the wound in the usual way in order to avoid all risk of infecting the buried sutures. He only recommends this operation to those who possess considerable skill in doing plastic operations, and in securing a snug, accurate adaptation of the parts.

In the discussion DRS. GEORGE H. NOBLE of Atlanta and J. WESLEY BOVÉE of Washington, D. C., added their testimony to the usefulness of the method described by Dr. Kelly, certain features of the technic of which they modified.

(To be continued.)

REVIEWS.

A MANUAL OF HYGIENE AND SANITATION. By SENECA EGBERT, A.M., M.D. Illustrated. Philadelphia and New York: Lea Brothers & Co., 1898.

THE work before us, which the author states is written with a view to "give a plain statement of the fundamental principles and facts of hygiene and sanitation, . . . based on American practice," fills a long felt want, for several reasons. First, books of this nature are very often too technical for every medical practitioner, for, as a rule, they embody many details of engineering which are somewhat foreign to the usual studies of medical men. Secondly, works of this description are either too cumbersome or not sufficiently explicit for general use.

We find the subjects of air, food, and water treated in a most comprehensive manner. The chapter on ventilation and heating might convey to the intelligent laity many interesting facts which could be advantageously employed, especially at this season of the year. The subject of filtration of water is ably treated and is accompanied by very good illustrations of apparatus employed, both in private as well as in city supplies. We find, further, such essential subjects as personal and school hygiene, and the removal and disposal of sewage most admirably discussed.

The book is prefaced by an interesting history of hygiene as a science. The illustrations scattered through the text, which are carefully selected and well reproduced, make the book more interesting to the reader, and a complete index enhances the value of the volume as a handy-reference work which might find a place in any professional or private library.

AN EPITOME OF HUMAN HISTOLOGY. For the use of Students in connection with lectures and laboratory work. By ARTHUR W. WEYSSE, A.M., Ph.D., Instructor in Biology, Massachusetts Institute of Technology, Boston. New York, London, and Bombay: Longmans, Green, & Co., 1898.

THE author states distinctly that this is not a text-book and that it is not intended "for those who have neglected their work and are anxious to acquire in a few hours, facts enough to pass an examination." The purpose of the book is to give to the student a brief, yet clear and definite, sketch of all the necessary data in the study of human histology, so arranged and classified that in a short time he may easily recall and memorize the lessons taught and studied. The subject is arranged and presented in a masterly manner, and cannot fail to be appreciated by every student. All of the recent advances made in histology have been recognized and incorporated and the book as it stands is a good example of our knowledge in this branch of medicine.

The book contains ninety pages, nearly twenty of which are devoted to a very full index, and is printed on very good paper. The binding is a serviceable one.

THERAPEUTIC HINTS.

For Ringworm of the Scalp.—PERKINS of London has achieved excellent results even in old chronic cases by the use of common salt. The salt, finely pulverized, is mixed with a small amount of vaselin and rubbed twice a day into the affected area (previously shaved). An eschar generally forms after two to four days of this treatment, which is then discontinued, a simple ointment being substituted. The surface then cicatrizes over and the hair begins to grow in normally.

Douche for Gonorrheal Vaginitis.—

	Quininæ sulphatis		gr. xv
	Ac. carbolici, Ol. thymi	aa	gtt. xxx
	Glycerini		ʒvi.

M. Sig. For vaginal douche. One tablespoonful in a quart of hot water 2 or 3 times a day.—*Lutaud.*

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIII. NEW YORK, SATURDAY, DECEMBER 24, 1898. NO. 26.

ORIGINAL ARTICLES.

A STUDY OF SIXTY CASES OF LOBAR PNEUMONIA OBSERVED IN BELLEVUE HOSPITAL, NEW YORK.[1]

BY A. ALEXANDER SMITH, M.D.,

OF NEW YORK;

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE AND CLINICAL MEDICINE IN THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE.

THE cases on which these studies are based were observed in the wards of Bellevue Hospital. As occurs in all large charity hospitals most of the subjects were in an unfavorable condition to tolerate any serious disease. All cases, even of those patients who were moribund when brought into the hospital were included. Five of these died within twenty-four hours after admission, two being cases of septic postpartum, one a case of cancer of the pancreas, stomach, liver, and intestinal glands, and two were suffering from pulmonary edema. One case was that of a pregnant woman brought in during labor, the patient dying within half an hour after admission. Almost all of the patients gave a history of having been badly housed, insufficiently clothed, and poorly fed, and most of them were subjected to great exposure in their occupation. As will be seen in the summary, a large proportion of them were addicted to the use of alcohol to a greater or less extent. As an example of the conditions under which they were living before admission, five of the patients walked to the hospital after the beginning of their illness, two of them on the second, and two on the third day. In two instances of these the temperature was between 105° and 106° F. when the patients were admitted. One of these patients walked in the night a distance of two miles, another a distance of a mile and one-half, both on the third day of the disease, to reach the hospital. Of these five patients who walked to the hospital, too died soon after admission from pulmonary edema; the other three recovered, the pneumonia in these three cases running a fairly regular, typical course.

It will be noticed that only two of the patients had pleuritic effusion as a complication, and in not one of the 60 cases did an empyema occur as a sequel, rather an unusual experience in 60 cases of pneumonia observed in hospital practice. Another unusual feature is that of the 9 patients more than fifty years of age only 2 died. Four who were between sixty and eighty recovered. The age of greatest mortality was that between thirty and fifty, 12 of the 17 deaths occurring between those ages.

As occurs in a very large proportion of the cases in large charity hospitals, complications or co-existing diseases were present in most of the cases, and in all but 1 of the 17 fatal cases. Several of the patients had been sent in to the alcoholic ward of the hospital and developed pneumonia after admission, whereupon they were transferred to the medical wards.

The highest temperature observed was usually on the day of admission to the hospital, due probably to the exertion and excitement attendant upon the moving of the patient. The highest temperature observed was 105.8° F., in a patient who had just been admitted. In two fatal cases the temperature at no time reached 102° F., but in these cases the pulse was rapid, feeble, and irregular from an early stage of the disease. Chronic nephritis was a very frequent complication and was present in five of the fatal cases.

Of the sixty consecutive cases of pneumonia treated in my service at Bellevue Hospital during the season of 1897–98, there were forty-two men and eighteen women. Of these seventeen died, being 28⅓ per cent.

Habits.—Alcoholics (marked), 38 (male 33, female 5); moderate drinkers, 14; temperate, 8.

Conditions Preceding the Attack.—Exposure, 22; exposure and heavy drinking, 14; debility, 4; following a "cold," 3; submersion in water after heavy drinking, 1; post-partum sepsis, 2; indefinite, not known or no history, 13; following fracture of ribs, 1.

Onset of Disease.—Chill with rigor, 23; chilliness, 24; doubtful, 9; no chill, 4.

Termination.—Crisis, 27; lysis, 19; died before determined or had complicating disease, 14.

Of 27 cases ending in crisis the crisis occurred on the fifth day in 2, seventh day in 14, eighth day in 1, tenth day in 1, and day not known (previous history indefinite) in 9.

Involvement.—Right lung entire, 1; right upper and middle, 1; right upper and right lower, 6; right lower and middle, 2; right and left upper and lower, 2; right lower and left lower, 2; wandering, right lower, right upper, and left upper, 1; left upper and left lower, 3; left upper, left lower, and right lower, 1; right upper, 7; left upper, 5; right lower, 13; left lower, 14; middle lobe, 2.

Of 12 apex cases 5 were fatal, and of these 5 fatal cases 4 patients were forty years of age or over. Of the five fatal apex cases 4 patients were markedly alcoholic. Of 29 cases in single lower lobes or middle lobe 7 were fatal.

Of the 60 cases recorded 23 patients had marked delirium. Of the 12 apex cases 8 patients had marked delirium. Of the 29 single lower-lobe cases 13 patients had marked delirium. Of the 12 apex cases 5 patients had other complications than delirium.

An upper lobe, with or without a lower lobe, was involved in 26 cases out of 60 and 8 deaths out of the total 17 occurred from these 26.

Albumin, at least a trace, was found in the urine of all the patients where opportunity for examination occurred except in 4 cases. One patient was six-months' pregnant and went to full term.

Cold compresses to chest in 10, to abdomen in 2 cases, every hour in the daytime, every two or three hours at night.

Of the 60 cases recorded 38 subjects were large consumers of alcohol. Of the 17 fatal cases, 14 patients were distinctly alcoholic, 1 was a moderate drinker, and the remaining two were women—one a septic post-partum (hopeless) case, the other chronic nephritis.

Of the 60 patients 22 had no complication nor marked delirium. Of the 17 fatal cases all but 1 patient had serious complications or coexisting diseases.

List of Complications or Coexisting Diseases.—Marked delirium, 23; chronic endocarditis, 2; typhoid fever, 2; tuberculosis, 3; chronic nephritis, 7; pregnancy, 2; pleurisy with effusion, 2; carcinoma, 1; post-partum sepsis, 2; pericarditis, 1; fractured rib, 1; erythema nodosum, 1.

Treatment.—All of the patients were given water to drink. Indeed, they were urged to take water very freely. During the acute stage the diet consisted chiefly of milk, broths, soups, jelly, and eggs, when the patient was able to take them. Kumyss and matzoon were also allowed. When pain was a marked feature during the first days of illness morphin was used sufficiently to relieve it. In some cases in which pleurisy was a complication and the pain severe adhesive-plaster straps were applied to the side to restrict movement. As most of the patients were alcoholic and delirium was a prominent feature, with wakefulness, hypnotics were used, but always with care, the choice of these depending somewhat upon the amount of delirium. In some of the cases 20 to 30 grains of chloralamid at night gave satisfactory results. In others a combination of bromid with moderate doses of morphin seemed to work more satisfactorily. Sulphonal and trional were also employed in the early stages in some cases and apparently produced no depressing effects, but, on the contrary, refreshing sleep resulted. Alcohol in the shape of whisky was used in a large proportion of cases, but more especially because the patients were alcoholic and on account of its sedative effect rather than as a cardiac stimulant. The quantity of whisky varied from 4 to 8 ounces in the twenty-four hours, but in a few cases this quantity was increased to 10 or 12 ounces.

Cathartics were used as indicated and as a routine practice in cases which were seen early in the development of the disease.

Of the coal-tar preparations, a combination of phenacetin and caffein was employed in some of the cases seen early in which there was severe headache, dry skin, high temperature, severe muscular pain, and marked restlessness. This was given in small

doses, phenacetin 5 grains and caffein 1 grain, and repeated every three, four, or five hours, the indication being the moderate reduction of temperature, if along with this reduction the unpleasant symptoms mentioned were decidedly relieved. This combination was not used in any instance after the third day. Digitalis was used only in cases in which there was valvular cardiac disease with predominant dilatation and because of this condition of the heart.

Strychnin and glonoin were used in a large proportion of the cases as a routine and from the beginning of the treatment. Strychnin was given in doses of from $\frac{1}{60}$ to $\frac{1}{30}$ of a grain every three or four hours according to the severity of the case and the effect produced. Glonoin was given every two hours in the daytime and every three hours at night in doses of $\frac{1}{60}$ of a grain.

Baths in the form of the bed-bath or sponge-bath were given in cases in which there was high temperature (above 103° F.) and marked restlessness. No plunge-baths were given. These baths were not given at regular intervals, but according to indications, *i. e.*, temperature of 103° F. and over with marked restlessness. The temperature of the baths ranged from 75° to 65° F. In ten cases compresses were applied to the thorax at a temperature ranging from 75° to 65° F., the indication being the same as for the giving of the bed-bath or sponge-bath. So special pains were taken in the fitting of the compresses. A sheet doubled four times was dipped in water at the temperature named and was then wrapped around the patient from the axillary region down to the hips. The temperature of the water varied with the temperature of the patient. The compress was applied to the thorax because this was the most convenient region and not because it was believed that it would produce any special effect upon the process going on in the lungs, but rather for its effect as an external application of cold. It was noticeable that in the cases in which the compress was applied there was at first objection on the part of the patient, but within twenty-four hours it would be asked for and welcomed. The compresses seemed to reduce the temperature, diminish the frequency and increase the force of the pulse, quiet the nervous system, and produce refreshing sleep. Almost invariably the patient said that he was more comfortable after the compresses had been resorted to.

In two instances, as a matter of experiment, these compresses were applied around the body from the lower part of the thorax down to the thighs, over an area corresponding in size to the thoracic region, with the result that they had the same effect as when applied over the thorax. It is simply a modification of the bath and seemed to act by stimulating the respiratory and circulatory centers, reducing temperature, and quieting nerve perturbation.

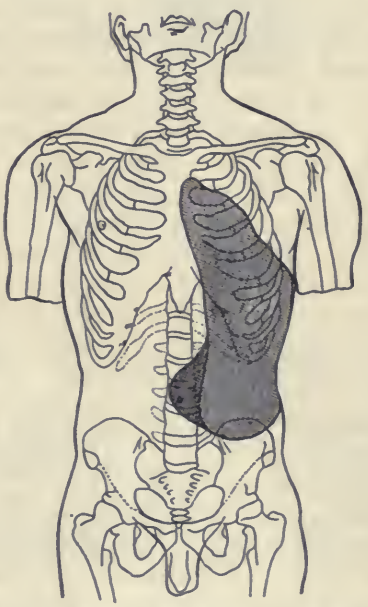
In cases in which pulmonary edema developed or in which cyanosis was a marked feature, inhalation of compound oxygen gave great relief. This was administered freely for from six to eight minutes at a time at intervals of from half an hour to two hours, depending upon the severity and persistence of these two symptoms.

A FURTHER REPORT ON SOME INTERESTING CASES OF VARIOUS FORMS OF ANEMIA.

BY H. A. HARE, M.D.,
OF PHILADELPHIA;
PROFESSOR OF THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE.

IN the MEDICAL NEWS for March 27, 1897, I published the histories of a number of cases of anemia, on the further progress of which I desire to report at this time. I also wish to record another case of considerable interest from a number of points of view. Perhaps the most interesting case, however,

FIG. 1.



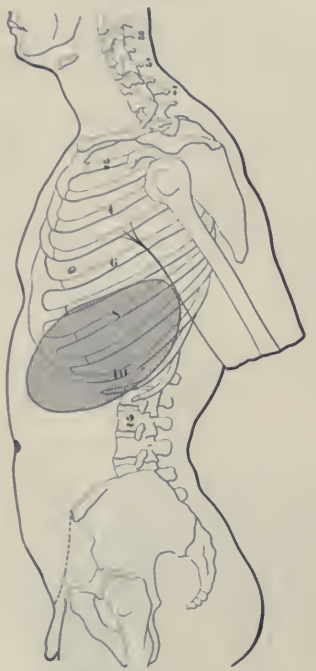
D. M. B. Splenomedullary leucemia. January 12, 1897. Slightly shaded portion shows area of cardiac and splenic dulness on percussion. The dark portion near the umbilicus shows the additional splenic area discoverable on palpation.

is that of D. M. B., who suffered from the splenomedullary form of leucemia, this report concerning him being fourteen months after the report already referred to, and nearly two years after he first came under observation. The report in the MEDICAL NEWS indicated an extraordinary improvement during the three months he had been under treatment,

the white cells decreasing from about 500,000 to 19,000, the red cells increasing from about 2,300,000 to 4,000,000, and the hemoglobin from about twenty-five per cent. to more than sixty per cent. The area of splenic dulness was also diminished to an extraordinary degree.

At the present time the patient is ruddy looking, has been at his work for nearly eighteen months, and is very healthy in his general appearance. His spleen is smaller than at the last report, as indicated in the drawings reproduced in this article, the latest having been made on March 31, 1898.

FIG. 2.



D. M. B. Splenomedullary leucemia. Size of spleen after fourteen months of treatment.

The examinations of this patient's blood, for which I am indebted to Dr. J. C. Da Costa, Jr., have been as follows in their results:

February 2, 1897: Hemoglobin, 67; erythrocytes, 4,000,000; leucocytes, 19,000; proportion, 1–210. February 16, 1897: Hemoglobin, 70; erythrocytes, 4,100,000; leucocytes, 80,000. March 3, 1898: Hemoglobin, 70; erythrocytes, 2,500,000; leucocytes, 44,000. Of the 44,000 white cells, 70.8 per cent. were polymorphonuclear cells, 6.8 per cent. small lymphocytes, 5.6 per cent. large lymphocytes, 2 per cent. eosinophiles, and 14.8 per cent. myelocytes. No transitional cells.

March 31, 1898: Hemoglobin, 82; erythrocytes, 4,800,000; leucocytes, 32,000. Of the 32,000 white cells 77.5 per cent. were polymorphonuclear cells, 4 per cent. lymphocytes, 8 per cent. large lymphocytes, 4.8 per cent. eosinophiles, 2.4 per cent. myelocytes, and 3.10 per cent. were transitional. Of the red cells there were 9 normoblasts, 25 megalocytes, and no poikilocytes.

The great difference in the white cells on the dates last named was not represented by the patient's appearance, as he seemed hearty and well, although he returned on March 3rd to make sure that he was not retrogressing, as he did not feel quite so well. On March 31st he expressed himself as feeling perfectly well, returning only because he had been directed to do so. He now considers himself perfectly well.

This case is extraordinary in that while all the symptoms were at one time very marked, his life and usefulness has been prolonged for a long time, and his health is so good. He has been using arsenic in full doses with some constancy, this drug having been of great benefit from the inception of his treatment.

The second case, that of splenic anemia, J. D., was referred to as follows in my original paper: "The large number of lymphocytes (eighty-four per cent.) in this case would apparently place it under the head of that somewhat rare type of leucemia called lymphatic leucemia, but there is an entire absence of enlargement of the lymph-glands, and, what is far more important, the increase in lymphocytes is purely relative, the total number of white cells being actually lower than normal. Aside from this state of the white blood-cells, the case might well be classed with what has been called pure splenic anemia, or splenic pseudoleucemia. Thus, we find the enlarged, and at times painful, spleen, the fact that the disease is commonly found at this patient's time of life, and in his sex, and that the anemic fever has also been present. Further than this, in splenic anemia we often have a decrease in the number of red cells to one-half, with a similar falling off in hemoglobin. Banti has regarded this state as a purely splenic form of pseudoleucemia, or Hodgkin's disease."

He reentered the wards of the Jefferson Hospital on February 22, 1898, and stated that after leaving the hospital he had continued taking ferratin three times daily, and attended the out-patient department until the following June. Then he stopped taking medicine, but did no work until July, when he resumed his vocation as barber, and had continued working at that until the day of admission. Since leaving the hospital he had felt entirely well until a week previously, February 14th, on which day he had quite a severe attack of epistaxis from the left nostril lasting about five minutes. On the same day he also felt pain and tenderness in the region of the

spleen. The epistaxis had recurred nearly every day since, sometimes coming on while in bed, and the pain in the splenic region had progressively increased in severity. During the previous week he had suffered from slight headache upon arising in the morning. During the previous three days the pain had been most severe in the median line about two inches above the pubes. He stated on the day of admission that he had had no headache, no epistaxis, and that splenic tenderness was not so severe as on the day preceding. His temperature was 98⅗° F., his pulse 86, and his respirations 22. The urinary examination on February 23, 1898, was negative. The blood examination on February 23, 1898, showed the color index 1.25, hemoglobin 40 per cent., red cells 1,620,000, white cells 7000. A differential count showed polynuclear cells 58 per cent.; small lymphocytes, 17 per cent.; large lymphocytes, 19 per cent; transitional, 2 per cent.; eosinophiles 2 per cent., and myelocytes 2 per cent. On February 28th it was noted that since entering the hospital he had had no epistaxis, and the splenic pain and tenderness had entirely disappeared.

In June, 1898, he again entered the wards, with extraordinary pallor, dyspnea, and splenic pain. His blood examination gave the following result: Polymorphonuclear cells, 66 per cent.; lymphocytes, 26 per cent.; eosinophiles, 4 per cent.; transitional cells, 2 per cent.; myelocytes, 2 per cent., and there were poikilocytes, macrocytes, microcytes, normoblasts, and gigantoblasts. The total hemoglobin was 25 per cent., red cells 1,800,000, and the white cells 7000. This man has now had a number of these relapses, but in each instance they have occurred after hard work, and he has recovered as soon as he had rest and good food. He has at no time been well, but has earned a living.[1]

The third case, that of F. R., is of considerable interest. As recorded in my earlier paper, already referred to, he entered the Jefferson Hospital in May, 1894. His family history and his previous history were good except that when he was twenty years of age he had had a severe attack of serous diarrhea, and that fourteen years before he had had croupous pneumonia, from which he made a good recovery. In April, 1893, he began to have nausea with occasional attacks of vomiting, with poor appetite, and his skin became quite yellow. Diarrhea also came on. At this time, after the temporary improvement in his condition, he progressively became worse, and on May 18th he presented a markedly anemic appearance, the lips and ears being almost bloodless, and the tongue pale. His temperature ranged from 99° to 101° F., and the respirations from 24 to 30. The conjunctivæ were infiltrated with a lemon-yellow fat, and there were numerous fresh and old hemorrhages into the retina. The veins and arteries of the retina could scarcely be distinguished on account of the pallor of the blood. There was a soft systolic murmur at the base of the heart and at the second left costal cartilage. In other words, the patient had every appearance of one suffering from pernicious anemia.

An examination of his blood revealed only 973,000 red cells and 7000 white, the hemoglobin being 15 per cent. A month later the red cells numbered 664,000, the white 5000, and the hemoglobin was 10 per cent. He was placed on ascending doses of arsenic, with the result that his blood steadily improved, so that on September 12th the red cells were 3,800,000, the white cells 10,000, and the hemoglobin 60 per cent. He was then discharged, in September, 1894, and went to work again in the pine forests of Pennsylvania, but was readmitted on August 28, 1896, with all his old symptoms present. An examination of his blood on September 1st showed 1,180,000 red cells, 5000 leucocytes, and 35 per cent. of hemoglobin. His blood progressively grew worse until September 22d, when it was recorded that he had 886,000 red cells, 3800 white cells, and 23 per cent. of hemoglobin. Full doses of arsenic and sulphate of iron improved his blood so that on February 18th there were 4,360,000 red cells. In the account of his case published in the MEDICAL NEWS for March 27, 1897, I said: "He presents every aspect of being cured, although the possibility of a fatal relapse is always to be remembered in this disease." In this connection the following letter, written under date of July 2, 1898, in reply to a letter of mine in regard to his health, is of very great interest, although no blood count has been possible owing to the fact that he lives at a distance from Philadelphia. This patient considers himself in good health more than four years after the time that he first came under observation. He writes:

"Yours of a recent date is before me, and in reply would say that I am very much improved from the time of leaving Jefferson Hospital, and weigh at the present time 205 pounds, the only apparent trouble at present being some soreness in chest and feet. If you could suggest any remedy for my feet and chest, please advise."

The fourth case, the patient ill with pernicious anemia (S. S. D.), died in November, 1897, having steadily failed during the preceding six months. No autopsy was allowed. His hemoglobin, which, on

[1] This patient presented himself in my office December 10th, and stated that he was quite well. His object in calling was to ask for "any kind of work."

February 24, 1897, was 35 per cent., fell to 28, then in another month had risen to 45 per cent., and a month later was 35 per cent. It fell finally to 20 per cent. His red cells fell from 2,250,000 to 1,108,333, then rose to 1,850,000, and then fell to 1,225,000. Poikilocytes were numerous, but normoblasts and megaloblasts were absent. This case simply illustrates the temporary improvement and final fatal ending of ordinary pernicious anemia.

The sixth patient (Case V.) died, and his case has already been reported.

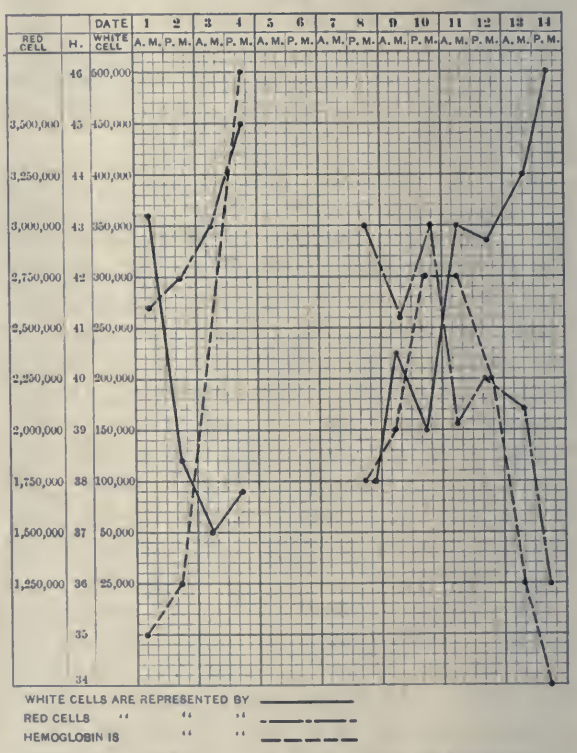
The last case I shall report in this paper has not been reported before. It is one of splenic leucemia. It is interesting because, being a private patient, he was under continuous observation for nearly fourteen months, and many blood counts were made. The autopsy, also, was of unusual interest.

A. B. C., aged forty-one years, came under my care in April, 1897. His family history was entirely negative. He had the usual diseases of childhood and enteric fever at nineteen, from which he made a perfect recovery. In 1881 he was greatly exposed to cold and wet, and suffered from subacute rheumatism of an articular type, which persisted more or less severely up to the time I saw him. The knees and ankles were the parts most involved. In 1883 he had a severe attack of croupous pneumonia, and since 1892 had had several attacks of influenza. In 1887 he contracted syphilis, but was treated for it rigorously for twelve months, and had no lesions except the primary sore. The patient had always used alcohol freely. In January, 1895, he began to suffer from pain in the left side in the splenic area, and began to lose weight in March, 1895, when the spleen was found decidedly enlarged.

On April 10, 1897, when first seen by me, the splenic and hepatic swelling was very great. His girth at the umbilicus was forty-two inches, and from the tip of the ensiform cartilage to the lower edge of the spleen in the middle line was fifteen and one-half inches. The right edge of the spleen reached four inches to the right of the median line at the navel. There was edema of both legs, chiefly the left, owing to the pressure of the splenic tumor. His pulse was 84, soft and compressible, and auscultation revealed a systolic murmur, soft in character and characteristic of anemia, at the aortic and pulmonary cartilages. The urine was negative. At this time his blood showed the following changes: Hemoglobin, 35 per cent. of normal; erythrocytes, 2,640,000 per c.mm.; leucocytes, 395,000 per c.mm.; lymphocytes, 10 per cent.; mononuclear leucocytes, 12 per cent.; polynuclear leucocytes, 60 per cent.; eosinophiles, 8 per cent., and myelocytes, 10 per cent. There was slight poikilocytosis.

From this time on examinations of the blood were constantly made, at times as frequently as once every week. The accompanying chart clearly indicates the results of these counts during a peried of fourteen months. It is interesting to note that under the use of ascending doses of arsenic and iron there developed a progressive improvement in his blood as to an increase in hemoglobin and red-cells, and a decrease in leucocytes. The lines on the chart show how the white cells decreased as the red cells and hemoglobin increased during the early months. While no counts were made during August, September, and October, he continued the treatment in a modified dosage, so that on his return to my care in November he was in fair condition. It is interesting to note, also, that as the red blood-cells fell in November the white cells increased, and when the large doses of arsenic were repeated and he was under their influence, the red cells and hemoglobin increased and the white cells decreased a second time. Finally, when, in January, he could no longer take full doses of arsenic because his stomach rebelled and his face became puffy, the white cells progressively increased, and the red cells and the hemoglobin greatly decreased until he died. With noteworthy constancy, in the entire progress of the malady the hemoglobin rose and fell with the red cells, and the white cells fell and rose in inverse ratio. A few days before his death the hemoglobin was twenty-eight per cent., the red cells 1,800,000, and leucocytes 706,000.

FIG. 3.



Blood chart of A. B. C. Fatal case of splenic leucemia.[1]

Notes of the Autopsy.—Body of an emaciated male, with rigor mortis moderately marked. The

[1] The names of the months during which the blood examinations were made should be substituted at the head of this chart for A.M. and P.M.—[ED.

abdomen was greatly distended, and there was edema of the feet, legs, penis, and scrotum. On making an abdominal incision, scarcely any subcutaneous fat was encountered; the muscles of the abdominal wall were very pale and friable. The abdominal cavity contained 2000 c.c. of clear yellow fluid. Beneath old scars on the abdominal wall were numerous peritoneal adhesions; these scars were the result of frequent tapping. The peritoneum was somewhat thickened and reddened, and more opaque than normal. The surface of the omentum was roughened, and scattered over its surface were numerous tumor-like enlargements of an average diameter of 1 mm. The lower margin of the liver in the right mammary line extended 5 c.m. below the costal margin; the upper margin extended to the upper margin of the fourth rib; the left lobe of the liver extended downward 10 cm. below the ensiform cartilage; the left margin of the left lobe extended to the left 5 cm. beyond the left nipple line. The lower border of the spleen extended downward to within 7 cm. of the symphysis pubis; the right margin extended to the level of the nipple. The stomach lay in the angle formed by the separation of the inner borders of the liver and spleen, which was on a level with and just to the right of the umbilicus. This viscus was, therefore, pushed downward, forward, and to the right of its normal position. The transverse colon was pushed downward and occupied a position just anterior to the stomach; the left half of the transverse colon lay beneath the lower border of the spleen, and was consequently much prolapsed. The right pleural cavity contained 100 c.c., of clear yellow fluid, but was otherwise normal, as was its fellow. The pericardium was normal, and contained 20 c.c. of clear yellow fluid. The heart was large and very flabby; the left side was slightly contracted. The heart substance was pale and moderately friable. The right auricle was punctured and cultures made from the blood. The small amount of blood which exuded was fluid and light in color.

The spleen was enormously enlarged. It weighed 5500 grams (about 14¾ lbs.). Its transverse circumference was 48 cm. (20 inches), and its longitudinal 86 cm. (34½ inches). The organ was decidedly notched on its inner and outer borders. Over its surface were numerous white scars of irregular outline and size. On section its substance offered great resistance to the knife, it being much tougher than normal. As regards color, the substance presented the usual peculiarities. In situations where scars occurred it was found that this tissue extended down into the substance of the organ; these masses of scar tissue were irregularly pyramidal in form, the apices extending toward the central portion of the organ; they had the appearance of the remains of old infarcts. The splenic substance for perhaps a millimeter around these areas was much redder than in other situations. The liver was enormously enlarged, weighing 6300 grams (approximately sixteen pounds, ten ounces). On section it was seen to be pale in color and of normal consistence. The adrenals were somewhat enlarged and darker in color than usual, the substance of normal consistence. The left kidney was displaced to the right, and lay in front of the spinal column, its long axis parallel to that of the spinal column. Over the surface of this kidney there were numerous cysts from .5 to 3 cm. in diameter. The substance was pale and quite tough. The pyramids were not well marked off from the cortical portion, which was somewhat diminished in amount. The weight was 250 grams. The right kidney, with the exception that there were no cysts on the surface, was in the same condition as its fellow; weight, 285 grams. The ureters were normal. The bladder contained a considerable quantity of opaque urine. Its walls were extremely thin, but otherwise the viscus was normal.

The stomach and intestines were normal. Within the entire alimentary canal dark, grumous masses were found, which were evidently more or less altered blood. Within the mesentery several enlarged lymphatic glands were found; they were generally of a uniform faintly reddish color, and contained but little fluid. In one instance, a gland was found, the substance of which was rather grayish in color, and scattered through its substance were numerous hemorrhagic areas.

A section of the right femur was made, and the bone was found to be very hard. The marrow was much firmer than usual, and was of a reddish-gray color. It seemed to be less firmly attached to the surrounding bone than usual.

Allowing for the temporary improvements seen in the life history of ordinary cases of splenic leucemia, this patient certainly greatly improved and finally held his own for a time under full doses of arsenic. This was shown in the patient's general health, by his blood, and was recognized by himself. While this disease is one with a necessarily grave prognosis, the fact that arsenic can so completely check its progress and improve the condition of the patient, at least for a time, is of great interest.

INTESTINAL OBSTRUCTION DUE TO INTUSSUSCEPTION AND VOLVULUS.[1]

BY JOHN F. ERDMANN, M.D.,

OF NEW YORK;

PROFESSOR OF PRACTICAL ANATOMY AND CLINICAL PROFESSOR OF SURGERY IN THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; ATTENDING SURGEON TO GOUVERNEUR AND ST. MARK'S HOSPITALS.

DR. EDWIN MARTIN, in a paper read before the Philadelphia Pediatric Society on November 9, 1897, stated that he was particularly impressed with the rarity of intussusception, as out of eight hundred personal communications sent out by him, most of them being answered, the returns brought him records of but fifty-four cases, and that men of the

[1] Read before the New York State Medical Association, October 19, 1898.

widest experience in surgery, medicine, and pediatrics reported that they had never seen a case. Such a statement is apt to be not only misleading as to the frequency of this disease, but also has a tendency to create an undesirable impression of diagnostic acumen upon the profession at large. It has been the fortune of the author to see four cases within a period of four-weeks' time, during February and March of this year, and three more cases within the three years preceding, while a typical chronic case came under his observation a number of years ago, and two cases, chronic in nature and due to malignant growths, were seen in the practise of a brother surgeon during the past year and a half; in addition two cases were reported to him during the first half of the year. Such a series of cases under the observation of a single operator tends to the belief that the disease is much more frequent than most authors admit.

Cases of intussusception may be classified according to their intensity after the manner of Raffinesque, as *ultra-acute*, death occurring in twenty-four hours; *acute*, terminating within the first seven days; *subacute*, lasting from two to four weeks, and *chronic*, lasting from three weeks to months before a fatal determination.

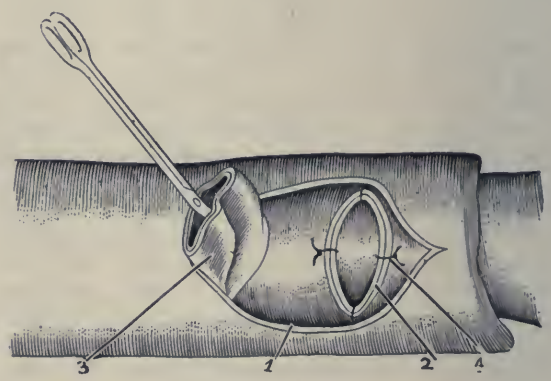
Intussusception is the cause of fully thirty per cent. of all cases of acute obstruction. The greatest proportion of cases of intussusception, fully fifty per cent., occur in children under ten years of age, and of these more than fifty per cent. occur in infants under twelve months. Between the ages of five and forty to fifty the number of cases diminish, and after forty or fifty the frequency of occurrence is again noted. This condition may be explained upon the grounds of periods of debility, occurring in infancy and extreme adult age.

Anatomically the following varieties of intussusception will answer: The *ileocecal*, in which the ileocecal valve forms the apex of the intussusception; *ileocolic*, in which it is made up of ileum and cecum passing into the colon, and the *ideal* or *enteric* variety made up entirely of small intestine. Of these the enteric is the most frequent. Very frequently upon autopsy intussusception is found that is due to post-mortem changes and not to any condition existing before the death of the patient. These cases can readily be excluded by their previous history.

The causative factors of intussusception are variously ascribed to former conditions of health or preceding physical conditions; conditions causing diarrhea; factors of a pathologic origin, and factors that originate in the anatomy of the intestine. Factors of an anatomic origin include long and lax mesentery, although the author has been unable to demonstrate the existence of such an anatomical condition in any of his cases. Another of the anatomic causes and the one receiving greatest weight is the musculature of the intestinal coats. These muscle-fibers, the longitudinal ones primarily and the circular secondarily, produce the intussusception through irregular peristalsis in the following manner: Contraction of the longitudinal fibers occurs with a retraction of a portion of the gut from below into the part undergoing the irregular peristalsis; after a time contraction occurs in the circular fibers when a grasping of the intussusception takes place, which may and frequently does continue to such a degree as to produce strangulation. It is this contraction of the circular fibers that prevents the reduction of the mass in the irreducible non-strangulated and gangrenous types.

Among the pathologic causes are tumors, usually of the internal coats, which by their weight produce

Fig. 1



Barker's operation.

1. Incised intussuscipiens.
2. Proximal end of intussusceptum.
3. Distal end of intussusceptum.
4. Suture in entering and returning gut.

the irregular peristalsis. These are chiefly polypi and endotheliomata; also imperfections in the intestines, as Meckel's diverticulæ. One case was reported by the author in the *New York Medical Journal* of April, 1898, the history of which is included in this paper. Another of these cases of Meckel's diverticulæ as the causative factor in this disease occurred recently in the practice of a fellow surgeon.

Under the preceding physical conditions, it is stated that a child of robust physique is less liable to suffer from this condition than one more puny and delicate. Our cases do not lend any weight to this argument, as we find that the majority were well-nourished children. Former conditions of health, barring a process which is accompanied by diarrhea or by a pathologic condition of the intestines, apparently cannot be considered as factors of any

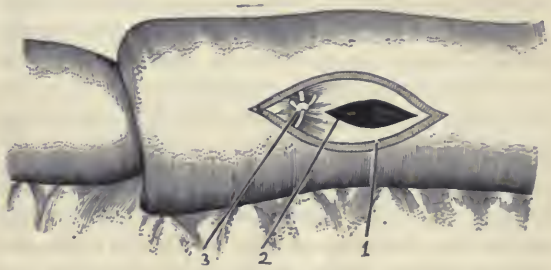
great importance, except in patients in whom debility is well marked, these having less resisting power to intestinal diseases. It would seem to the author that all conditions and factors which tend to produce diarrhea and vomiting are primarily the cause of the irregular peristalsis, excluding, of course, those cases classed as distinctly pathologic in origin, and these causes are changes of temperature, exposure of the abdomen, due to insufficient clothing during the day and improper protection at night; foodstuffs that disagree (and here we must include the artificial foods, as many children cannot take some of these without evil effects, as well as unripe or decayed fruits, tainted meats, etc.), and finally injudicious feeding by overloading the stomach, as seen in many children; also, insufficient precaution in preparing foods, etc.

The symptoms and signs of intussusception are pain, vomiting, tenesmus, blood in the stool or a bloody mucus dejection, restlessness, tumor, and later, manifestations of obstruction, peritonitis, and sepsis. Pain has been an ever-present symptom in the author's cases. The abdomen is tender to the touch, manifested by the patient if too young to speak by flinching or crying upon palpation. Vomiting has been present in but three cases and these were the cases of more than twenty-four-hour's duration when seen by the author. It is well to remember that in many of these cases the onset is frequently preceded by diarrhea and vomiting, so that in many of the cases in which vomiting was an early manifestation it may have been but an accompaniment to the pre-existing condition of health.

There may be, and frequently is, an evacuation of more or less extent, due to feces in the intestine below the seat of the intussusception. This evacuation is not accompanied by blood or bloody mucus. Later there are passages which consist of blood and mucus or may be largely composed of blood or mucus simply tinged with blood. The presence of blood is readily ascribed to the obstruction producing strangulation of certain parts of the vessels and increasing arterial and venous pressure sufficient to produce hemorrhage by diapedesis and even by rhexis. Tenesmus is frequently observed following the first few passages. The patient does not lie quietly in bed during the early hours of the disease, but is constantly tossing and moaning and continues doing so until the gut is reduced or until gangrene and sepsis are established. If after an injection the restlessness and moaning cease, *i.e.*, during the first twenty-four to forty-eight hours, it can be safely stated that reduction has taken place.

The proverbial sausage-shaped tumor cannot be found in all instances. In the case of three patients, operated upon by the author and palpated by most able diagnosticians, no tumor was to be felt through the abdominal wall, but the symptom-complex was so perfect of intussusception that abdominal section was performed and a tumor found. The reason was readily explained as in two cases the tumor was found well under the ribs in the left hypochondriac region and in the third well under the right lobe of the liver. Digital examination frequently proves the presence of this condition, as the palpating finger comes in contact with the mass in the rectum. In one of the author's cases, in which no tumor was palpated externally, it was thought that the very tip of the finger came in contact with a fold of intestine foreign to the anatomy of that part. This disappeared upon injection. The child became quiet and slept for eight hours, when it again became restless and had another pink mucus dejection. Nothing was felt upon digital examination but upon opening the abdomen the tumor was found in the left hypochondriac region.

FIG. 2



Paul's operation.

1. Incision through intussuscipiens.
2. Incision through intussusceptum.
3. Ligature above the metal tube.

Later the symptoms become aggravated, obstruction is complete, the pulse is rapid and feeble, and all the manifestations of peritonitis and sepsis are present.

The treatment consists of mechanical, expectant, and operative procedures for the relief of the intussusception. Under the mechanical methods we have the use of air and water distention of the bowel. The danger incurred in the use of air is an overdistention with rupture of the intestine. Little can be said in favor of this method of reducing the intussusception as it does not have the mass-like pressure action that is produced by the use of water. As the pressure cannot be gaged as easily as when using water, the method should be passed over at the present date. Enemata of water to be successful should be used during the first twelve or twenty–four hours, *i.e.*, before adhesions form, but in all cases of no matter what duration, it should be used first, bearing in mind the fact that the reservoir should not be more than four feet in height from the body

of the patient. These are best given with the patient in the inclined posture or suspended by the feet. Although water passes the ileocecal valve with great ease in the cadaver and has been demonstrated time and again as passing in the living, it should be borne in mind that enemata are prone to prove unsuccessful in cases in which the tumor is above the transverse colon. This is due to the fact that when the tumor is above the transverse colon, the effect of the water pressure is more of a pulling action upon the receiving gut than of a driving action upon the apex of the intussusception. Massage of the abdomen and the tumor, when found, should be done while the water is being introduced. Although the dangers of the use of water are similar to those of air, they are less prone to occur, owing to the weight pressure upon the apex of the tumor being followed more frequently by reduction than by the use of air. It cannot be too strongly stated that this type of taxis should not be used with any greater degree of frequency or duration than manual taxis in a strangulated hernia; for the conditions are certainly allied. Should the injection be followed by no result, operative procedure should be advocated as strongly as one would in a hernia that has not responded to taxis.

When pain is not severe, obstruction not complete, and tenesmus with bloody mucus not marked, the case can be carefully watched, as these are the cases likely to become chronic and later be followed by a spontaneous cure by sloughing off of the tumor. Certainly, with the present state of aseptic operative procedures, this method of treatment can never more be considered seriously. We know that these cases can never be claimed as true cures, owing to the likelihood of stricture formation following the sloughing process, and that they are very prone to be followed by obstruction demanding at a later day an emergency operation which is likely to have a more serious aspect than would the question of primary operation for intussusception.

The author cannot agree with those who state that children bear operations poorly, and is quite satisfied that when the cases are seen early, say during the first thirty-six hours, the chances for recovery of the patient are extremely favorable. One of the writer's cases of recovery reported in this paper, a child under seventeen weeks of age, was operated upon during the first thirty-six hours. Another, a child of four months and twenty-two days old, was operated upon during the first twenty-four hours. The relationship of recoveries between strangulated hernia and intussusception with regard to previous duration is very similar. The longer the duration, the greater the mortality, due in each instance to the same causes—shock, exhaustion, gangrene, and sepsis.

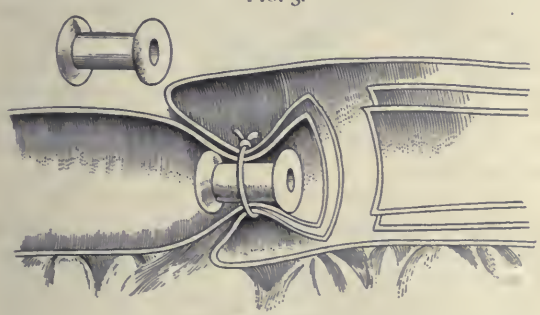
After exposing the tumor the following procedures are in order: reduction, artificial anus, entero-anastomosis, partial resection, typical (?) resection. Reduction is best accomplished by pressing through the intussuscipiens upon the apex of the mass in such a manner as to drive the intussusceptum through its receiving coat. Traction upon the extreme ends should not be practised, as it is liable to result in injury to the walls of the gut of such extent as to be followed either by immediate rupture or destruction of portions requiring a further and more protracted operation. Pressure from behind need never be severe enough to injure the integrity of the intestine in any way, as in all cases in which there are neither adhesions nor gangrene the reduction is extremely easy. In the irreducible variety, no matter what the condition of the gut, one of the more severe operations is indicated.

The establishment of an artificial anus requires no words from the writer, for all are thoroughly familiar with the steps of procedure and the indications warranting it. When the patient's condition will admit of further procedure than the formation of an artificial anus, partial resection or typical resection should be done. An entirely unnecessary operative procedure, and one productive of as much shock and requiring as much time as an operation of more radical results, is entero-anastomosis. Partial resection, *i.e.*, resection of the intussusceptum through the receiving coat or the sheath, is advocated by Barker, Grieg Smith and others, and a modification of it is suggested by Paul and described in the London *Lancet* 3, 30, 1895. The operation of Barker (Fig. 1.) consists in first placing a row of sutures at the entering end of the intussusception, so as to include the sheath or intussuscipiens and the intussusceptum, then making a longitudinal incision in the ensheathing portion, placing suitable ligatures about the mesentery of the ensheathed portion, cutting off this ensheathed portion, and removing it through the gut, or if long enough, through the anus. A few sutures are placed in the cut proximal ends, all hemorrhage is checked, then the longitudinal cut in the sheath is sutured and finally the abdominal wound is closed. This operation is indicated only when no preventive adhesions exist between the invaginated and ensheathing portions.

As a modification of this operation the writer would suggest that the row of sutures uniting the intussusceptum to the intussuscipiens be omitted, and that before cutting off the intussusceptum the healthy entering gut be brought through the longitudinal slit, first tying off the mesentery then cutting off the in-

tussusceptum and removing it and completing the operation after the manner of end-to-end anastomosis described by Maunsell. Paul's operation is a modification of that of Barker, and, we take it, was advocated with a view to shortening the duration of the operative interference, but has the objectionable feature of requiring the surgeon to add another instrument, a light metal tube with expanded ends, to his now overstocked store. It is also an operation that can be performed only in selected cases, *i.e.*, those in which the caliber of the gut is retained to a degree sufficiently large to admit such a tube or improved device. The operation is performed as follows (Fig. 2.): After a preliminary row of sutures connecting the intussusceptum and intussuscipiens, the gut is cut longitudinally as in the Barker operation; then the returning and entering layers are cut, and the tube is pushed into position. A stout ligature is then tied about the intussusceptum so as to include the tube; finally the intussusceptum is cut

FIG. 3.



Paul's operation.
Longitudinal section, showing the position of the metal tube.

off. The incision in the outer layer is then closed in the usual manner. The features commending the operations of Barker and Paul are rapidity and diminished danger of soiling the peritoneal cavity. An objection is that the operation is more than likely to be followed by a diminution of the caliber of the gut.

In chronic intussusception, advancing in nature, the treatment resolves itself into an end-to-end anastomosis (after reduction as far as possible has been performed). Typical resection with end-to-end anastomosis should only be undertaken in those cases in which the patient's condition will warrant prolonged interference. The choice then lies in the hands of the operator between the use of Murphy's button, the Maunsell operation, and direct end-to-end anastomosis. Owing to the fact that more than one intussusception can take place, it is advisable to thoroughly examine the entire intestinal tract before closing the abdomen. Owing to the great variance in the mortality-rate as given by three most excellent observers during the past three years, Rydygier, 1895, seventy-five per cent.; Wiggin, 1896, twenty-two per cent., and Gibson, 1897, fifty-three per cent. the writer intentionally avoids presenting statistics which might further bewilder the reader.

CASE I.—Reported before the Section on Surgery, New York Academy of Medicine; March, 1895. *Medical Record*, p. 475, 1895.

Male, eight and a half months old, seen on the fourth day of the disease. Enemata had been unsuccessfully employed. No tumor was palpable either through the abdominal wall or per rectum. Celiotomy was performed and an intussusception of the enteric variety found in the left hypochondriac region. The mass was partially reducible; the remaining irreducible portion, almost six inches in length, was gangrenous. This gangrenous portion was removed and an end-to-end anastomosis with the Murphy button done. Septic peritonitis existed at the time of the operation. Death occurred within twelve hours.

CASE II.—Reported in the *New York Medical Journal*, April 16, 1898. F., male, aged nine years, was seized at four o'clock Friday afternoon in August, 1897, with colicky pain in the abdomen, limited to the right side and of rather severe character. During the night he vomited the contents of the stomach and some bile, and passed a large quantity of blood and clots by the bowel. There was marked tenesmus and frequent attempts to have a movement of the bowels throughout the following day, but with no further result than the passing of mucus and blood. His temperature was said to have been normal, while the pulse was slightly increased. On Sunday his condition showed all the evidences of severe shock, and upon palpating the abdomen a rather elongated tumor could be mapped out in the right side. In the absence from the city of Dr. Carl Beck the case was referred to me by the family physician. I saw the patient at nine o'clock on Sunday night and found the following condition: Countenance anxious, temperature 101° F., pulse 128, abdomen distended and tympanitic, painful to the touch, and a sausage-shaped tumor extending from the right iliac fossa to the costal cartilage of the tenth rib. I had the patient transferred to St. Mark's Hospital, opened the abdomen at ten o'clock, about fifty-eight hours after the onset of the symptoms, and found an intussusception of the enteric variety, the apex of which was within six inches of the ileocecal junction.

The mass was irreducible and gangrenous, and the mesentery was gangrenous to within an inch of its attachment to the lumbar column. In addition, the intestines were deeply engorged and a quantity of pus was found in the cavity. Resection of the mass and an end-to-end anastomosis with the Murphy button was performed, the abdomen thoroughly washed out with salt solution, and a gauze pack placed down to the anastomosis. The patient bore the operation very well and reacted nicely. During the two days following the operation he was given sixty cubic centimeters of Marmorek's serum with-

out any evidences of improvement. The condition of sepsis increased, and the patient expired at the end of the fourth day following the operation.

Upon examining the specimen a mass about two inches long was seen protruding at the distal extremity which was made out to be Meckel's diverticulum that had become inverted and evidently was the cause of the intussusception. Upon cutting the specimen open it was found to measure thirty-three inches in length. This extreme length was due to the tight manner in which the intussusceptum was packed in the ensheathing intussuscipiens (Fig. 4).

Case III.—Female, aged four months, seen September 18, 1897. Condition extremely bad. Rapid, feeble pulse; cyanosis; apathetic. Temperature 101° F.; abdomen distended, quite tympanitic. No tumor upon palpation, due to abdominal distention. Previous history vague; had been ill for a week or

Fig. 4.

2. Ileum.
3. Meckel's diverticulum (inverted) and intussusceptum.

more. The family stated that seventeen physicians had seen the patient during her illness. A diagnosis of intussusception had been made by the majority and operation advocated by some but was refused. Finally the family begged that an operation be performed. This was done within an hour of admission and an ileocecal intussusception found, readily reducible, but a general septic peritonitis existed and death followed within twelve hours.

Case IV.—Female, seventeen weeks old, well-nourished. Had had a previous day of diarrhea, and was seized with pain, restlessness, and bloody mucus dejections. Sent to the writer by Dr. Francis Huber, February 18, 1898. Enemata had been unsuccessfully tried. No mass or tumor palpable either by rectum or abdominal wall. Operation performed within the first eighteen hours; tumor found in right hypochondriac region and was of the ileocecal variety. Reduced readily. Patient stood the operation nicely but was taken ill with pneumonia; then another lobe became involved; finally recovery resulted. Suppuration occurred in the superficial layers of the wound. Discharged in five weeks.

Case V.—Female, exactly five months old. Sent to the writer by Dr. Joseph Huber, February 23, 1898. Patient had suffered from tetany for some weeks. Bottle-fed and poorly nourished. History of previous diarrhea and of intussusception of a few hours' duration. When seen by the writer there was pain, restlessness, blood-tinged mucus stools, but no tumor upon abdominal palpation. By digital examination a protruding mass high in the bowel could just be felt. Several enemas were given, and upon digital examination the protrusion could not be felt. She was placed in bed and slept quietly for eight hours. Upon awakening she became restless, and had a blood-tinged mucus stool. Operation was performed. The tumor was found in the left hypochondriac region, extending down to the lumbar region. It was of the ileocecal variety. The tumor was fixed in this region and upon searching for the cause of its irreducibility it was found that a hernia of the small intestine had taken place through the foramen of Winslow. Several coils being reduced before the fixation of the intussusception could be relieved, the tumor was readily displaced and reduced by pressure through the intussuscipiens upon the apex of the intussusceptum. This child also recovered, but during three weeks following the operation there was absolutely no evidence of union in the abdominal wound. The intestines protruded upon several occasions. Secondary sutures were placed twice, and upon two occasions blue pus was present upon the dressings. During the third week repair began. The child was discharged between the sixth and seventh weeks.

Case VI.—Male, thirty-eight years of age, admitted to Gouveneur Hospital, March 17, 1898. When seen by the writer he stated that he had had colicky pain that morning. Examination: Slight evidence of shock; pain in abdomen; local tenderness in left hypogastric and lumbar regions; vomiting; had a rather large bloody mucus stool. Palpation: Very sensitive upon left side; a tumor elongated in shape could be felt in the left lumbar region. Three pints of saline solution were given after a three-pint simple enema; both were negative in results. Bloody stools continued at intervals. Operation not indicated by patient's general condition. March 18th. Three-pint injection of salt water followed by bloody mucus only. Pain eased some. March 19th. Enema of three pints of soap and water. Pulse 100.2° F. Tumor disappeared. Calomel, 10 grains, and eleterin, $\frac{1}{10}$ of a grain, were given. March 20th. Large movement. March 21st. Patient discharged.

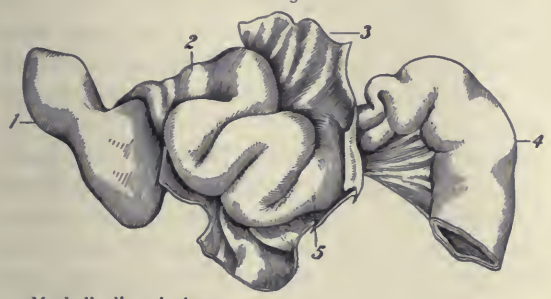
Case VII.—This case occurred in the practice of Dr. M. Dantes during March, 1898, who cited the history to me with a view to treatment. Female, aged three and one-half months, ill two days when seen by Dr. Dantes. She had had diarrhea and vomited a few times during these days. When seen there were bloody-mucus stools, pain, and restlessness. No tumor found by abdominal palpation, but evidences by rectal examination. Enema proved of no avail. Operative interference refused; child died on the twelfth day of the disease with all the evidences of a septic peritonitis. During the latter

days of her life foul-smelling discharges were evacuated but no sloughs.

VOLVULUS.

Volvulus is a disease of advanced life and consists usually of an axial rotation of a portion of the bowel with occlusion sufficient to cause either partial or complete obstruction. The twisting may be and frequently is followed by gangrene of the engaged loops or portion of the bowel. The causes are chiefly anatomical as predisposing with exaggerated peristalsis as an excitor. The anatomical cause is either a preternaturally long mesentery or a normal mesentery elongated, possibly by a weight in the bowel or

FIG. 5.



1. Meckel's diverticulum.
2. Intussusceptum.
3. Intussuscipiens split open.
4. Ileum.

hernia. About fifty per cent. of all cases have been found involving the sigmoid, and here the cause is eminently the long mesosigmoid, usually found giving great mobility to this portion of the intestines. The next frequent site of volvulus is the lower ileum or cecal region. Men are said to suffer from volvulus four times more frequently than women.

The symptoms of an attack of volvulus are sudden onset of pain more or less general in the abdomen and finally localized; occasionally a tumor corresponding in outline to the intestine, this tumor varying on percussion from a dull to a highly tympanitic note; pulse accelerated; obstruction following after the bowel is emptied below the point of twisting. These symptoms may suddenly disappear as a result of self cure by untwisting or as a result of an injection. In case this does not occur a progressive peritonitis, first localized then generalized, with concurrent gangrene, takes place.

The treatment resolves itself into the use of enemas and operative interference. If an enema has been used successfully there is usually an evidence of gas or feces coming from the anus or retention of the fluid for a length of time, while the abdominal symptoms are immediately ameliorated.

It has recently been stated that numbers of cases of volvulus of a minor degree untwist either during palpation of the abdominal wall or as a result of peristalsis due to some cathartic agency. Should injections *plus* massage fail, then celiotomy should be performed with a view to releasing the twist, and carrying out any of the following operative procedures found necessary. These are, in cases not requiring excision of gangrenous gut, the stitching of the mesentery so as to shorten it or to prevent the twisting recurring, or the removal by excision of a portion of the long and lax sigmoid with its mesosigmoid, and then performing end-to-end anastomosis. Where gangrene has taken place the course of procedure is exactly as in the case of gangrene in strangulated hernia or intussusception. During three years of an emergency service only three cases have occurred in Gouveneur Hospital. One of these came to the writer in 1896. The patient, a female about thirty-eight years of age, was moribund at the time seen, with a history of a week's illness, onset with sharp abdominal pain, complete obstruction after a small movement; then localized pain in the left lower region of the abdomen. Distention was marked when seen by the writer; pulse 140; temperature subnormal. The patient was cyanotic. No operation; death in a few hours. Autopsy: A volvulus was found involving the sigmoid and rectum with gangrene of fourteen inches of gut.

The second case occurred in the service of the late Dr. O. J. Ward in August, 1897. A male, aged 37 years, with a history of epigastric pain of slight character for some time. Five days prior to admission had an attack of diarrhea followed by complete obstruction. Upon admission severe pain was localized in the epigastrium, general abdominal tenderness, dulness over lower abdomen; tympanites over the right hypochondrium; pulse 120; respiration rapid; first evidence of vomiting since illness began. Abdominal section was performed. General fibrinous peritonitis with a volvulus of a part (?) of the small intestine was found. This was readily reduced after breaking up some adhesions. Patient died in thirty hours.

The third case occurred in the early summer of this year in the service of Dr. John Rogers and was seen by the author. The patient was an elderly Polish Jew with a large irreducible hernia. When seen by the writer he was suffering from symptoms of a strangulated hernia, but upon operation by Dr. Rogers, a volvulus of the ileum was found with other contents of the sac. The patient died within forty-eight hours from shock (?).

Although this third case was not a typical case of volvulus, nevertheless, the twisting evidently was the cause of the irreducibility, the patient having suffered from a reducible hernia for years.

THE PRESENT STATUS OF ANTISEPTICS USED IN SURGERY OF THE EYE.

By J. A. BACH, M.D.,
OF MILWAUKEE, WIS.;
PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS.

THE constantly exposed position of the conjunctival sac, together with a favorable temperature, sufficient moisture, and proteid matter enough to encourage bacterial growth, make this organ the almost constant habitat of micro-organisms. Here they find many safe retreats in glandular openings and other recesses, and under certain conditions give rise to purulent processes. Under ordinary circumstances Nature has, however, happily provided counteracting influences which prevent bacterial development to any dangerous degree. The abundant blood supply of the eyelids and extra-orbital structures assures a local vitality great enough to make at least improbable any serious invasion of pathogenic organisms into these tissues. On the other hand, the wonderful and perfect drainage of a healthy conjunctival sac, together with its flushing apparatus, the lacrimal gland, are ample to dispose of unusual numbers of bacteria in time of health. It is, however, not always so when through some cause or other these natural safeguards become in a measure debilitated.

In a large percentage of those cases in which surgical interference is indicated, a concomitant defect in the power of the eye to protect itself is also present, hence, infections due to lack of special precautions have often taken place. It is evident to all observers that, since the general recognition of the principle of antiseptic precautions in operations on the eye, failure of good result through infection has been rare indeed. It is but recently, however, that it has been observed that germicidal agents, which are used with so much confidence, do not deserve the foremost commendation for reliability in procuring brilliant results in eye surgery, and that, in fact, they often carry within themselves elements of the greatest danger to an eye that has been operated upon, especially if the deeper and more delicately nourished structures are involved. Chief among these dangers may be mentioned the incidental irritation these agents produce if used in the strength which experience teaches is necessary to accomplish destruction of pathogenic germs. To destroy the enemy of good healing in its hidden recesses by chemical agencies has been proved to be practically impossible without serious damage to the tissues and consequent lowering of their vitality. Within the last few years many tests have been made to determine the relative value of chemical antiseptics used in the eye. In all these tests it has been clearly shown that none of the antiseptics, though used in strong solution, would of themselves render the conjunctival sac aseptic, and that the incidental mechanical cleansing is a factor far more efficient than the antiseptic itself. In fact, irrigation and cleansing with normal saline solution has proved just as efficient to reduce the number of micro-organisms and render the eye surgically clean as when antiseptics of a chemical nature were used. The point of the greatest importance has been found to be the repeated cleansing by swabbing and irrigation combined, the quality of the solution, whether a chemical antiseptic or distilled water, being of no consequence. Once thoroughly sterilized by a process of frequent swabbing and irrigation, mild antiseptics, such as boracic-acid solution, etc., were sufficient to keep the surface in a surgically clean condition, while the stronger antiseptics would frequently set up irritation, itself detrimental to the best healing.

The nutrition of the cornea and of all the media of the eye is so delicately balanced that the slightest lowering of vitality will cause serious disturbances and thus invite infection, which these tissues otherwise might have resisted. The stronger antiseptics, consequently, are used less and less, and Nature's method of mechanical cleansing with the use of normal saline solution, or some other non-irritating solution, finds acceptance. In operations on the lids and appendages, where nutrition is always good, the character of solution is not so material, and no harm could result from using even the stronger antiseptics. Here, however, though harmless, the stronger antiseptics are not necessary, as the excellent blood supply in these structures is fully sufficient to guard against infection provided ordinary cleanliness is practised. It has been the practice of a number of prominent eye surgeons to wash out the anterior chamber after cataract extraction with a solution of boracic acid or some other mildly antiseptic solution. But even these have been found in many cases to favor inflammatory processes and have been largely abandoned for this special use. My experience has been that the quickest and most favorable healing with the least amount of irritation has been in those cases in which the stronger antiseptics, such as 1–2000 or 1–5000 sublimate, were avoided, and in which normal saline or boracic-acid solutions only were used to insure surgical cleanliness by repeated irrigation and swabbing after the more serious diseases of the lids and lacrimal apparatus had been cured by appropriate treatment. These cleansing processes have been generally begun a few days previous to operating on intra-ocular structures. On the other hand, I have

on different occasions found that a solution of 1–5000 sublimate not only irritated some eyes considerably but actually seemed to endanger good healing through such irritation. In this experience I am corroborated by many leading eye surgeons.

A source of great danger in operations on the eye is the improper or insufficient preparation of the instruments and general surroundings. To act strictly in conformity with the best teachings, based upon bacteriologic facts, one must have due regard for the influence of air currents and for commotion in the operating-room in stirring up dust. No amount of attention and care can always prevent infection when these precautions are not taken during an operation. In the preparation of the operator, as well as the instruments, the ordinary rules of aseptic surgery should be strictly adhered to. Shortly before the operation instruments can with great advantage be dipped into absolute alcohol and then thoroughly wiped under firm pressure with clean cotton wool, when after being boiled they are placed in a concentrated boracic-acid solution for immediate use.

The present tendency of the use of antiseptics in surgery of the eye is to discard the stronger and depend more upon obtaining asepsis by means of the weakest solutions together with mechanical cleansing. Experience and careful observation have proved this to be the safest and surest means of obtaining ideal results.

CLINICAL MEMORANDUM.

THE DIFFICULTIES OF DIAGNOSIS IN RUPTURE OF THE SPLEEN, AS ILLUSTRATED BY A CASE.[1]

By J. RIDDLE GOFFE, M.D.,
OF NEW YORK;
PROFESSOR OF GYNECOLOGY AT THE NEW YORK POLYCLINIC; VISITING GYNECOLOGIST TO THE CITY HOSPITAL.

ON February 3, 1894, I was summoned to Staten Island to see a boy who had been injured while coasting on a hand-sled, having been thrown violently against a tree. The tree was a sapling and in striking it he was doubled up around it, the point of impact being the left lumbar region. The boy was picked up in a state of profound shock and carried into the house. He was at once placed in bed and hot bottles applied. The local physician who was promptly called gave the boy stimulants and a hypodermic injection of morphin to control the shock and relieve the pain in the left lumbar region of which the patient complained. He rallied at the end of four or five hours. At this time he was unable to pass his urine and a catheter was used to empty the bladder. About ten ounces of urine was obtained and floating in it were a great number of minute blood-clots which upon settling completely covered the bottom of the ordinary chamber vessel.

The accident happened at about five o'clock in the afternoon and I saw the patient at 2.30 P. M. the following day. At that time I learned the above history and saw the three separate specimens of urine which had been secured and saved for my inspection. Minute blood-clots were apparently still in the amount described above. I recognized the boy at once, a tall, slender, swarthy complexioned young fellow, a Mexican, the son of a prominent citizen of Vera Cruz. He had presented himself at my office with letters of introduction upon his arrival at New York with his brother six months previously, for the purpose of attending a private school on Staten Island.

I found him lying on his back, comfortable in every way except for a slight headache. His pupils were contracted; skin normal; he was under the influence of small doses of morphin; temperature 101.5° F. There was no paralysis, no points of tenderness along the spine, no irritability of the stomach; pressure in the left lumbar region was painful. Dr. Walzer, who was in attendance and who continued throughout to share with me the responsibility of the case, had already made a diagnosis of probable trauma of the left kidney and with this I cordially agreed. The extent of the injury was apparently not sufficient to demand surgical interference. The expectant plan of treatment was adopted, complete rest, sufficient morphin to control pain, light diet and careful general nursing. He continued to pass minute blood-clots in the urine in steadily decreasing amounts for four days, when they disappeared, and complained of pain in the region of the left kidney for ten days, his temperature ranging daily between 101° and 102° F. All his symptoms gradually disappeared and at the end of three weeks he was allowed to sit up and three weeks later was permitted to go out walking for exercise. While walking with his brother he foolishly got onto the tailboard of a passing wagon, but at the imperative demand of the driver promptly jumped off. He was immediately taken with terrific pain in the left loin and epigastrium, attended with violent cramps and vomiting. He walked home with assistance but immediately went into a state of collapse, necessitating treatment similar to that employed at the time of the original accident. I had been seeing him at regular intervals and was now hastily summoned again. The symptoms of acute gastritis yielded promptly to morphin treatment but the temperature went steadily up during the following forty-eight hours till it reached 104° F., accompanied by all the signs and symptoms of a general peritonitis focused about the vermiform appendix. Upon consultation an exploratory laparotomy was decided upon with the idea of removing the appendix if conditions demanded it, and at the same time taking advantage of the opportunity thereby afforded of passing the hand into the abdominal cavity and exploring all the abdominal organs and their immediate surroundings. The left kidney still protruded itself in thought as the original seat of the difficulty, with the possibility of a perinephritic abscess. Accordingly an abdominal incision was made in the median line. A recent plastic exudation was present throughout the entire ex-

[1] Read at a stated meeting of the Northwestern Medical and Surgical Society of New York, December 21, 1898.

tent of the peritoneum, the appendix was elongated, swollen and congested and adherent to the omentum. It was removed. I then passed my hand, and arm as far as the elbow, through the incision and examined all the organs of the abdomen; the liver, the spleen, the kidneys, and the pancreas were all in turn grasped and carefully palpated. The size, the position, and the consistency of each appeared normal and no sign of an abscess was anywhere present.

The patient rallied favorably from this operative procedure, the peritonitis entirely disappeared and he convalesced for a week with all the evidences of having been relieved of the *fons et origo* of his trouble. At the end of that time his temperature began to rise daily, the stomach became irritable and, after repeated daily examinations, a point of fluctuation with slight bulging was discovered at the middle of the anterior border of the right lumbar muscle. This was freely incised and about four ounces of pus was evacuated. The cavity was explored with finger and probe but no lead in any direction could be found. The patient recovered from this procedure and improved steadily for nine days, when he was taken with a severe chill, rise of temperature to 104° F., and a drenching sweat.

One of the most prominent surgeons in New York was now called in consultation, and in his presence the patient was again etherized and the pus-cavity explored. By enlarging the wound and thus securing more room a lead was found and a long uterine sound could be made to pass its entire length following the concavity of the abdominal wall on its interior surface to a point directly over the pit of the stomach. At this point an incision was made on the tip of the sound and the latter pushed through. Withdrawing the sound and entering the pus-tract through the new incision the sound followed the curve of the diaphragm on its under surface obliquely to the left its full length. Through the new incision the pus-tract was flushed out with sterilized water but not much pus was found. It was not thought wise to do anything more. A drainage-tube was inserted, through which the cavity was washed daily. This evidently afforded freer discharge and gave relief. The temperature was reduced to normal and remained near that point for a week with satisfactory improvement in his general condition. Again the chills recurred with marked rise of temperature and exhausting sweats. The same consultant was asked to see the patient again. After carefully summoning all the facts in the case and sifting the evidence, the conclusion was reached that the left kidney or its immediate surroundings must be the source of the pus and an exploratory incision at the seat of that organ was decided upon. In deference to the wishes of friends the consultant was asked to do the operation and consented. The kidney was found normal in size, appearance, and consistency, and no evidence of the presence of pus in the neighborhood could be discovered. As no other surgical procedure suggested itself which offered as much prospect of relief as the one just completed, the kidney was restored to its normal position and the wound closed. No appreciable depression followed this operation; on the contrary the patient seemed possessed of renewed strength and all the symptoms improved. At the end of another week, however, the discharge from the sinus gradually diminished, the stomach became irritable and the exhausting chills, temperature and sweats again renewed their deadly work. An area of dulness developed at the base of the right lung and the liver seemed slightly depressed. The patient was now well-nigh exhausted but still full of courage and anxious to submit to whatever offered any relief. At this junction Dr. John A. Wyeth and Dr. Frederick Lange were called in consultation together.

They discovered the same area of dulness and agreed upon the existence of a subphrenic abscess. They were also agreed that some injury to the liver was probably the original and essential cause of all the trouble. Dr. Wyeth favored immediate evacuation of the pus. Dr. Lange thought it would be useless; he was willing, however, to favor it to the extent of being present. I therefore asked Dr. Wyeth to operate and Dr. Lange kindly assisted.

The best route by which to reach the pus seemed to be directly through the pleural cavity. Accordingly, three inches of rib was resected, and while pressure was made to prevent the ingress of air the pleural cavity was entered. The edges of the incision in the thoracic pleura were then stitched in an ellipse to the diaphragmatic pleura and within this ellipse a trocar was passed through the diaphragm into the pus-cavity. About half a pint of pus escaped. Drainage-tubes were inserted, dressings and bandages applied and the patient put to bed. His condition improved a little after this procedure but it was apparent that his end was near. He had a severe fit of coughing the fourth night after the operation, during which his heart gave out and he expired. Necropsy revealed a normal condition of both kidneys and the liver but disclosed a ruptured and necrosed spleen. The anterior aspect of the spleen, however, was intact and surrounded by coils of intestines adherent to gave no suggestion to the eye or touch that it was injured. On breaking through the adhesions, however, there was disclosed a large pus-cavity and necrosis of the spleen to such an extent as to leave intact only the blood-vessels and the anterior shell of the organ.

The case is instructive in emphasizing the importance in all cases of internal injury, and especially when the diagnosis is uncertain, of prolonged rest, even to the extent of months. The boy in question had evidently recovered completely from the original injury, *i.e.*, the wound of the kidney and the spleen had both undoubtedly healed by primary intention. The violence done to the delicate tissue involved in the healing process, however, when the patient jumped from the cart, probably tore open the primary lacerations of the spleen, and suppuration occurred.

The behavior of the pus in that location is interesting. First there was awakened a general peritonitis, which was self-limited in spite of the continued presence of the pus. Then the pus took such a remarkable course in following the curve of the diaphragm from behind obliquely forward and to the right across the anterior face of the stomach

and accumulated at the border of the right lumbar muscle. As the tissues became weakened by continuation of the process and less resistant, the pus found a new channel and accumulated above the liver. In the light of the necropsy the only mistake made, if mistake it could be called, was in not pushing the exploration a little further at the time the left kidney was exposed. It is possible that direct communication with the necrosing tissue might have been established and the suppurating process stopped.

The operation for reaching the subphrenic abscess was one of the nicest bits of surgical work it has ever been my good fortune to participate in. The pity of it is that it could not have been productive of fruitful results.

MEDICAL PROGRESS.

A New Bread for Diabetics.—DAVIS (*Jour. Am. Med. Ass'n.*, November 5, 1898) recommends for the use of diabetic patients a flour made from one of the many edible pine nuts. It is fine, slightly yellow, and bland in taste. It contains no starch, and only seven per cent. of cane sugar, almost all of which is lost in the baking if the bread is raised with yeast. Bread and cake made from it is found to be an agreeable substitute for wheat bread. It must be used in moderation, however, or it will cause indigestion with loss of appetite and disinclination to eat this bread. The flour from which it is prepared is known as Chicago Sanitary Flour. It contains 55.65 per cent. of albumenoids, 6.42 per cent. of mineral matter, and 19.82 per cent. of oil. Sweet almonds contain 53 per cent. of oil, and cocoanut 70 per cent. This pine flour is, therefore, much less likely to cause indigestion than either of these nuts. These oils are not in themselves objectionable. On the contrary, they help to retard nitrogenous waste, and are therefore of service, if they do not derange the stomach. The best results are obtained if the patients are gradually accustomed to the change from wheat to diabetic flour.

Danger of Punching Out Bits of Malignant Tumors.—RICHARDSON (*Boston Med. and Surg. Jour.*, October 27, 1898) cites two cases from his personal experience to show the disadvantages of resting the diagnosis of carcinoma on the bits of tissue secured by a punch. In one of these the punch failed to bring out malignant tissue, and the patient went on in a false security until the disease had grown to such an extent as to render successful operation impossible. The bit of the breast of the other patient was proved by the punch to be not carcinomatous; but the clinical appearances were so contrary to this conclusion, that another punch-thrust was requested but refused by the patient. Two weeks later, the breast and axillary contents were removed, and it was noticed that there was infection of the pectoralis major, the pectoralis minor, and the axilla, in a straight line. This was, without doubt, a direct contamination of previously healthy parts by the exploring punch, for the nodules were of about the same size and age, and in the muscles, at least, they were the only ones found. Richardson says that the time has come when all suspicious breast-tumors should be explored so thoroughly that inspection and touch are possible. Even then a nodule may be overlooked. Exploration with a needle or a punch not only exposes the loose spaces about the tumor to infection, but it gives, by failing to extract a specimen from the affected spot, a false and highly dangerous sense of security.

The Prevention of Conception.—TREUB (*Centralbl. f. Gynæk.*, October 15, 1898) says that the principle, "No medical treatment without medical indication," does not meet all cases. Cosmetic operations are certainly justifiable. Not less so is the proper application of the pessarium occlusivum. This means of preventing conception is absolutely without danger. The danger for nervous persons lies rather in interrupted coitus and in the use of condoms. It is the duty of the physician to warn phthisical, epileptic, and neurotic persons that they ought not to have children. If a physician refuses, on account of Biblical or Talmudic law, to furnish to such persons the necessary knowledge to prevent conception, there is an end of medical scientific treatment. The significance of normal cohabitation is in general far too little considered. In men as well as animals the longing for coitus is not always associated with the desire for offspring, so that it is not right to speak of sterile intercourse as something contrary to Nature. Complete sexual abstinence is capable of working injury, if the attempts to overcome the desire for it put the physical and psychical powers of the individual to too great a strain. Voluntary sterility is allowable when the increase in the number of children would make it impossible that all should be properly brought up, or when the wife is not in physical condition to bear children. Preventive measures are abused by the rich, but they are too little used by the poor.

The Difficulties of Defecation in Infants.—MARTIN (*Jour. Amer. Med. Ass'n*, November 5th) says that the imperfect development of the lower part of the intestine of infants causes them to strain at stool. The infant's rectum and sigmoid flexure are deficient in muscular elements, and hence the power of peristalsis cannot be present to the degree necessary for adult defecation. Furthermore, the relation of the peritoneum to the rectum of the infant also contributes to the difficulties of defecation, as does the relatively great length of the descending colon and sigmoid flexure. The third feature which tends to obstruct defecation is the rectal valve. The presence of such a valve has been denied, but Martin found it in each of more than three hundred subjects examined by him. In most cases there were three valves, although in some cases there were four and in others only two. The valves are particularly well developed at birth, when they span one-half of the diameter of the gut. The bony pelvic outlet in the newborn infant measures, in its transverse diameter, 1.27 cm. (slightly more than half an inch). The pubococcygeal measurement is even less, while the average distensibility

of the sigmoid flexure is four or five times these measurements. All these facts explain how difficult it is for an infant to expel any other than fluid or semifluid feces. The practical lesson is that by means of diet, hygroscopic suppositories, and fluid injections the fecal matter should be kept from passing in a solid state.

Traumatism and Appendicitis.—SMALL (*Med. Record*, September 10, 1898) says that traumatism plays an important part in the development of appendicitis. The original idea that foreign bodies, such as grape-seeds or fecal concretions, set up attacks of appendicitis, has been generally given up. Later, the theory was advanced, and is still widely held, that catarrhal conditions in the cecum are the real cause of the inflammation in the appendix, and the recent epidemics of influenza with accompanying enteritis, are made to explain the great increase in late years in appendical trouble. Still, this does not explain why so large a percentage of cases is found in young adult males. The reason for this, according to Small, is their more frequent exposure to accidental injuries and strains, and the strong contractions of the abdominal muscles occurring in their work. The increase of abdominal pressure thus caused forces a part of the contents of the cecum into the appendix. In support of this theory the writer cites thirteen cases occurring either in his own practice or in that of his friends in which the traumatic history seemed clear. He thus sums up our present knowledge upon the subject:

1. That general prevalence of catarrhal conditions of the bowels, perhaps as an accompaniment or result of the grippe, is responsible for a large part of the general increase in prevalence of appendicitis.

2. That accidental injuries, strains, and work demanding strong contraction of the abdominal muscles may be held accountable for the greater prevalence of the disease in males.

3. That such injuries and strains act by forcing material, loaded with the bacteria which produce appendicitis, from the cecum into the vermiform appendix.

4. That in consequence of the irritation of such material, or from some other cause, these germs here find a favorable soil for their multiplication and development.

5. That in common with other germ diseases a time of incubation must elapse (for the multiplication of these germs) before symptoms sufficiently marked to prove characteristic of appendicitis can appear.

6. That the disease is of growing medico-legal importance, as many cases are of traumatic origin, and may, therefore, give rise to proper suits for damage or valid claims against accident-insurance companies.

Anesthesia of Anemia.—KOFMANN (*Centralbl. für Chir.*, October 8, 1898) says that he has found that the finger, or hand, or any part of the body that is absolutely free from blood becomes anesthetic. Therefore, instead of injecting cocain or using chloroform for operations upon the extremities, he simply applies a tight elastic bandage so as to render the part absolutely free from blood. After the anemia has continued for fifteen or twenty minutes, or, in some instances, for half an hour, he can operate freely without the patient experiencing the least sensation. He has proved the accuracy of this method in a number of instances, and is much pleased with it, inasmuch as he avoids the unpleasant after effects of cocain, and finds it necessary to use this remedy only in operations upon the trunk or head. In operations upon these parts he uses Schleich's method of cocain anesthesia. Chloroform he has given up almost altogether. It finds its place merely in particular instances.

THERAPEUTIC NOTES.

Menthol in the Treatment of Migraine. — FRIESER (*Münchener med. Wochen.*, August 30, 1898) looks upon menthol as a most valuable remedy in the treatment of migraine. When an attack comes on he either washes out the stomach with lukewarm water containing a little menthol, or if this is not practicable he directs the patient to drink a quantity of hot water and administers valerinate of menthol. The following is a favorite prescription:

℞ Menthol valerian. . . . . 3 j
Aq. dest. . . . . 3 v
Syr. capillor. vener. . . . 3 vj.
M. Sig. Fifteen drops every two hours.

It is important to improve the diet of anemic individuals by giving them iron and artificial foods. These he usually prescribes in the form of ferratin and somatose. The diet of constipated patients must be especially looked into. Daily irrigation of the bowels with lukewarm water containing a little glycerin, lukewarm sitz baths, abdominal massage, and electricity will be found of service in combating constipation. Fluid extract of cascara is a valuable internal remedy. The writer has little faith in the treatment of headache by antipyrin, antifebrin, phenacetin, salophen, salol, or lactophenin. If the pupils are greatly contracted a powder made in accordance with the following prescription may be given every two hours:

℞ Caffein. citrat. } aa . . . gr. viiss
Menthol }
Quiniæ sulph. . . . . gr. xv.
Div. in chart. No. X. Sig. One powder every two hours.

Patients with widely dilated pupils may inhale ether from a handkerchief, two or three drops at a time. Valerianate of menthol should also be given in the interval between the attacks of migraine. A permanent cure can be effected in many patients.

Menthol-Iodol for Use in the Nose and Throat.—To overcome the unpleasant odor of iodol, which has been found so valuable in the treatment of catarrhal and ulcerative processes of the nose and throat, it is recommended to incorporate with it one per cent. of menthol which serves also to produce a refreshing sensation in the parts treated.

For Vomiting in Pertussis.—

℞ Menthol . . . . . gr. i
Sacchari albi . . . . . gr. xii.
M. Div. in chart. No. VI. Sig. One powder every two hours.—*Baginsky.*

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed *exclusively* to THE MEDICAL NEWS will after publication be liberally paid for (accounts being rendered quarterly), or 250 reprints will be furnished in place of other remuneration. When necessary to elucidate the text, illustrations will be engraved from drawings or photographs furnished by the author. Manuscripts should be typewritten.

LAWYERS' FEES—DOCTORS' FEES

NEW YORK CITY or at least the non-legal portion of its inhabitants, for perhaps the legal fraternity considered it too mere a bagatelle to deserve even passing notice, have been not a little interested in the fact that has come to public attention during the past week that a lawyer may receive a $5000 fee and forget all about it. No one we are sure has the slightest doubt that the distinguished lawyer who denied absolutely having received the aforesaid fee, though it was afterward clearly proven that he had received it, was eminently sincere in his denial. It would simply seem that $5000 fees are such common occurrences in a great lawyer's everyday life that he cannot reasonably be expected to recall their receipt with absolute assurance if any considerable time has elapsed since the event, or if he happens to have been at the moment of its presentation so busy with other or more important matters as not to have made an act of reflex consciousness and so impressed the trifle on his memory.

We do not know of many members of the medical profession who would be liable to be bothered by such an annoying slip of the memory. It may be, however, that our acquaintance with the upper-tendom of the medical fraternity is not extensive enough to warrant our making an absolute statement in the matter. For after all the two professions, law and medicine, are filled by men who come from the same classes of society, whose educations take about the same length of time and cost about the same amount of money. There is no special vocation of genius to the one nor relegation of intellectual featherweights to the other. The labor required to fulfil the duties demanded of the lawyer is at least no more exacting than that demanded of the physician. We do not think that it has ever been hinted that the work done by the medical profession was of less importance to humanity than that done by their brothers of the law, and they are quite as frequently successful in their efforts in behalf of those who consult them. It would be manifestly unfair then to think that the rewards gained by the lawyers were so much greater than those accorded to the doctors. All of which goes to prove, we think, that despite the fact that we may not know them there are a number of medical men in Manhattan, who may in moments of inattention pocket $5000 fees without reflecting thereon, and so may-hap demand them again. *O, fortunati minium!*

But why is it then that when the question of doctors' fees gets into court lawyers always insist on their excessiveness? One might think that the generous fees they collect themselves would make them realize that the value of the work of a liberal profession cannot be estimated by any cut and dried rules of trade, or commercial deductions as to the value of time. The value of a service in law depends upon the worth of it to the party for whom it is performed, and the following out of exactly the same steps of legal procedure has a very variable fee for its reward according to the circumstances of the client for whom it is done. Why the same rule should not hold for the services of a physician does not seem very clear. But the attempt to put such a principle into action by the doctor brings down upon him in case of legal complications the malediction of judge and lawyer, and almost inevitably leads to the extremely unpleasant predicament of having to accept a fee made more or less arbitrarily smaller by the court. We humbly submit that all this seems scarcely in accordance with the American spirit of fairness or with the high principles of equity our

legal brethern laud so justly. Let us hope that this little public reminder that "there are others" will give them a fellow feeling that will make them wondrous kind to the little seeming exaggerations that their brothers of the healing art may commit in the making out of bills.

HYSTERICAL SCOTOMATA.

UNDER the caption "Forgot Her Own Name" the New York daily papers at the beginning of the week were discussing the case of a woman who called up police headquarters by telephone to ask if search was being made for a missing person of her description who had completely forgotten her own name. The police took her to a hospital and her friends were found. The case proved to be one of hysteria and the symptom that attracted so much attention, the amnesia of her own name, while not of frequent occurrence, is not unique in medical literature. It is analogous to other functional disturbances that cause scotomata, dark or blank spots, in sentient or psychical processes. Genuine scotomata of vision occur frequently; scotomata, so to speak, of taste or smell, in which the faculty to perceive certain savors or odors is lost, have been noted and the irregular anesthesia that constitutes one of the stigmata of hysteria is nothing more than these blank spots in tactile perception. The psychical scotomata are perhaps rarer and they occur especially in the voluntary sphere, though it is unfortunately the custom to ascribe manifestations they produce in this field to a blameable lack of will power. Some of the very peculiar judgments of the hysterical are undoubtedly due to hiatuses in the logical reasoning power that can be best explained on the ground that certain parts of the nervous organism necessary for perfect ratiocination are not at the moment capable of functioning—cerebration scotomata.

"GRIP" OR "COLD."

MANY doctors in New York City have been seeing during the past few weeks a series of cases that have easiest ranged themselves under the diagnosis grip. The symptoms have been irregular and atypical and have differed in different cases. Often there has been no coryza or any other involvement of mucous membrane until after two or three days of illness. Sometimes there has been very little fever, though complaints of pains in the bones and other symptoms of general malaise have been frequent. Sometimes fever has been a marked symptom though there has not been much general disturbance; at times the pulse has represented the most disturbed function in the case.

Since the epidemic of influenza ten years ago there has been a tendency to attribute all irregular or atypical forms of what used to be called an ordinary cold to grip. There is danger that a word like this may, by seemingly satisfying the natural inclination to look for the cause of a thing, discourage investigation of real causes. It would not be the first time by any means that a word has been made to do duty as a mantle, voluminous as charity in the moral order, to cover a multitudinous pile of ignorance. But it seems scarcely worthy of our vaunted end-of-the-century science to bridge over a hiatus in our knowledge by a structure that is words, words and very little if anything more.

The cases sketched just above are by no means typically grippal; in fact, unless Pfeiffer's influenza bacillus could be demonstrated in them we see no good reason at all why they should be classified as grip. We would much prefer to hear them classed simply as "colds." Not that "colds" is not so indefinite and general a term as to be almost meaningless and to be eminently unsatisfactory as far as the science of etiology goes, but its use is a confession that we do not know the cause and further investigation is encouraged. The fact that these cases have all occurred within a few days does not take them out of the catalogue of colds, which in the winter time are prone under certain meteorological conditions to occur in numbers. The further fact that the cases have at times occurred in groups so as to appear to have a certain epidemicity or even contagiousness does not argue against their being "colds." For we suppose if a cold means anything it means a microbic invasion due to certain weather influences, to increase in number and virulence of certain bacteria and to the lowered resistive vitality of the patient. Let us have the attempt to differentiate some of these colds from one another, first clinically by noting the grouping of certain symptoms, and second etiologically by finding the bacteria or some of them at work under the varying circumstances.

THE EVOLUTION OF FOOTBALL.

IT is interesting to note now that the football season is practically over, and the New York Harvard Alumni have properly honored the victors of the year, that there has been an almost total absence of that somewhat blatant disapproval of the game, so usual a few years ago, by a press that published accounts of brutal prize-fights without a comment. The fact of the matter is, the evolution of football has made for gentler methods in its practice. As it has been played this year it is a striking example of what true American manliness has been able to make out of a sport that seemed essentially rough. Much remains yet to be done to mollify certain objectionable features of this character but the healthful development of the game may confidently be left to "the powers that be" under whose guardianship the difficulties to be met are thoroughly appreciated. Their gradual removal is persistently and successfully being accomplished.

The football field has proven the nursery from which, as recent history shows, many a self-forgetting hero has come. We are glad to chronicle the gradual disappearance of certain objectionable features of the game and to encourage its further evolution along lines that, while leaving it an arena for gentlemanly sport of the highest order in which the best qualities of rising young manhood are brought out (a thorough eraser of the effeminate ways that modern luxurious city life threatens to bring into vogue), will make it still worthier of the attention of the cultured classes whom it now so powerfully attracts.

SEWAGE AND OYSTERS.

WE print this week a résumé of the practical conclusions of the Committee of the British Association for the Advancement of Science, appointed especially to report on the effect of sewage on oysters. Now that the holiday season is here, when so many of the popular bivalves are consumed, it seems particularly timely. The report points out very clearly that oysters are extremely liable to be contaminated by sewage material present in the water in which they live. As during the last few years the neighborhoods of our great oyster bays have become more and more thickly populated, with a consequent discharge of sewage into the bays, it is clear that the danger from oysters is becoming every year greater. The near future will see the danger increase, not diminish, unless measures are soon taken to protect the oyster beds and properly dispose of sewage.

Oysters and milk constitute two articles of diet that are still very plentifully and very generally consumed in the raw state in this country. (Milk, at least, is not used to any great extent raw except here and in England.) Of late years public opinion and State and municipal regulation have done a great deal to secure for us pure milk, but it was only after the sacrifice of thousands of children's lives that this was accomplished, and even the present condition of affairs with regard to the milk-supply of many of our cities cannot be a special subject of congratulation. It is not probable that any such serious lesson will ever come from the use of oysters, for they are consumed by the more resistive adult. In more than one instance, however, precious lives have been sacrificed to typhoid because of the neglect of the plainest precautions in the matter of the sewage contamination of oyster-beds.

This matter evidently demands the most careful consideration. We are not great believers in the efficacy of the legal regulation of such matters, for it brings with it many evils, but we welcome heartily the recommendation of the English commission that the oyster-growers and dealers themselves unite for the protection of their products from sewage contamination. They owe it to the public, and, besides, to look only at the sordid side of it, if the present uncertainty in the public mind with regard to the possible contamination of oysters continues, there will be a large falling off in their consumption. If the notion once gains credence that oysters are absolutely safe eating only when cooked, the injury done to the oyster trade will be almost incalculable.

LAPAROTOMY FOR PENETRATING WOUNDS OF THE ABDOMEN.

TWO recent discussions bring this subject prominently into notice once more. Professor Senn is reported by our Chicago correspondent (MEDICAL NEWS, December 3) to have said that a certain number of gunshot wounds of the abdomen recover without operation, and that a man shot from before backward at the level of the umbilicus or above it has a fair chance of recovery without operative interference. He has held this opinion now for several

years, has confirmed it experimentally and strengthened it by his experience during the Spanish-American War.

In our issue of last week we report the discussion of the same subject at this year's meeting of the Southern Surgical and Gynecological Association. This association adopted unanimously at its meeting last year a resolution to the effect, that in penetrating wounds of the abdomen it is the duty of the surgeon always to make an exploratory incision, so as to definitely determine whether the abdominal viscera have been seriously injured or not. This year's discussion brought out very clearly the fact that our Southern brethren, whose opportunities for seeing gunshot wounds of the abdomen are comparatively much greater than those of Northern surgeons, are still practically unanimous in declaring for laparotomy in every case. Even Dr. Parker, who had seen recovery without operation in about fifty per cent. of the penetrating wounds of the abdomen received during the recent war, still believes in laparotomy *in every case* in civil life. In active warfare circumstances are different. The wounds produced by the small bullet with high velocity of the modern military rifle are not always such as permit extravasation of the contents of hollow viscera and do not seriously tear, as often as might be expected, important blood-vessels. During the recent campaign, too, the facilities for abdominal operative work were necessarily imperfect so that expectant treatment was under the circumstances very good conservative surgery.

In civil life, however, gunshot wounds of the abdomen are often produced by large caliber bullets, of comparatively low velocity, whose lacerating power is increased by their carrying with them portions of clothing (something the rifle bullets during the war did not do). When such wounds are treated in a hospital where all the facilities are at hand for aseptic exploration, it seems taking needless risk not to make assurance doubly sure by actual inspection. Exploratory laparotomy in every case would certainly decrease the mortality, for even Professor Senn admits that in his experiment in only four out of sixteen cases did the intestines escape injury, even with the wounds above the umbilicus. A perfectly aseptic exploratory laparotomy ought, on the other hand, to add practically nothing to the patient's risk if proper precautions are taken to avoid shock, by exposing the intestines only as little as possible during careful exploration, and by making provision for keeping them at body temperature.

To wait till symptoms of perforation show themselves is to invite a fatal issue in nearly every case. The symptoms immediately following the injury are almost invariably dubious in the extreme, so that no rule of safe guidance for operation can be drawn from them. A great many lives would undoubtedly be saved by immediate laparotomy. The mortality of the cases that proved after exploration to have no intestinal perforation or serious bleeding-points would practically not be raised, so that despite our war experience the old rule as to immediate laparotomy for penetrating wounds of the abdomen seems a very proper one. Especially is this true if the wound has taken place within a couple of hours after the taking of a full meal. It seems unquestionable that some of the favorable results of abdominal gunshot wounds during the late war, were due to the fact that soldiers received them after fasting for long periods, or that the wounded were suffering at the time from some form of diarrheic trouble, which, while decreasing their appetites, secured a thorough emptiness of the intestines in other ways. Even a defective quartermaster department and the tendency to intestinal diseases among soldiers do not seem in this view to be entirely without their compensation or their places in Nature's conservatism. Such factors must not, however, be allowed to influence to any serious extent the surgical policy that will obtain for the next few years in the treatment of abdominal gunshot wounds in civil life.

THE PHYSICIAN AND HUMANITY.

THE American Humane Association met in Washington last week and the event was made the subject for editorial comment by most of the medical journals of the country. The tone of the editorials generally might lead the casual reader to think that physicians, or at least medical editors, are unalterably opposed to the movement for the prevention of cruelty to animals. This is far from being the case. Medical men as a whole are deeply interested in everything that will lessen the sum of the world's suffering whether among human beings or our

brothers of the brute creation. Force of circumstances alone has put us in the false position of seeming opposition to the Humane Association's work.

An unreasoning fanaticism is endeavoring to secure such regulation of animal experimentation as will practically nullify its scientific work. As medical men we are convinced that a great deal has been and still more will be done for the relief of human suffering by animal experimentation. This will involve the infliction of a limited amount of pain on a limited number of animals but will save many a precious human life and many an hour of human agony. We weigh the one against the other. Like the great physiologist Ludwig, whose discoveries were all made by means of animal experimentation, though he was the President of the Leipzig Society for the Prevention of Cruelty to Animals, we feel a humane interest in animal suffering and yet find ample justification for encouragement of what our opponents are pleased to call vivisection.

It would be ideally better perhaps, if we could stop animal experimentation, but pain is a necessary evil in the present dispensation and the purposeful infliction on animals of slight amounts of suffering leads to the saving of large amounts of it to human beings. But it is not alone human suffering that has been lessened by such experiments. The amount of pain inflicted by scientists bears no ratio to the amount of torture from disease that has been saved animals themselves by the observations upon their fellow brutes.

There is a spirit abroad in English-speaking countries that is growing in strength and that augurs ill for the continuance of that freedom of investigation so necessary to successful scientific research. The growth of this spirit is partly due to the persistent propaganda of their notions by fanatic antivivisectionists, but is more to be attributed to a failure on the part of people generally to understand what is meant by animal experimentation. It is known that large numbers of animals are used for experimental purposes. It is supposed that they die in awful torture from disease and operative procedures. This is not the case and the chance to see the actual workings of one of these experimental laboratories would be the best proof of it that could be had.

Most of the stock in trade of the professional antivivisectionist, the stories of horrible torture, burning, mutilation, etc., are drawn from times long since gone by. Some suffering there is but the dreadful torments are figments of a too vivid imagination. Stevenson the well-known English novelist was, as might be expected from his tender sympathies, an ardent antivivisectionist. Once while on a visit to this country, he spent some time in a well-known sanitarium for consumptives. While there he learned that the physician in charge was experimenting on guinea-pigs with the then recently discovered tubercle bacillus. His first impression was one of shinking from the physician of whom he thought so much. His health necessitated his staying, however, and gradually he learned to appreciate all that might be accomplished for suffering humanity by observation of animals suffering from the same disease. He learned especially that Koch's demonstration of the bacillus tuberculosus, which could not have been made without tests upon animals, enabled the physician to detect the first onset of the disease, and often, though not as often as he might wish, to prevent its fatal progress. With opportunities of observation similar to those of Stevenson, most antivivisectionists would cease their propaganda. There are some, we are sorry to say, on whom even this would have no effect.

Is not the pledge of a practically unanimous medical profession a sufficient guarantee that by animal experimentation a great work is being accomplished for science and for humanity? Much of the unselfish, because disease preventive, work of the modern science of hygiene has been made possible through animal experimentation and the medical profession has encouraged it though the diminution of disease meant lessened revenues.

Much of the animal experimentation is carried on at great risk of disease or even death, if the slightest precaution should be neglected, yet there has not been lacking in recent times members of the profession to fill up the ranks and take the martyrs' places. Has the medical profession not the right then to ask that the regulation of animal experimentation shall not be allowed to pass into such hands as will seriously hamper or practically prevent it?

The recent meeting of the American Humane Association at Washington had for one of its main objects the discussion of means to ensure the passage

of the Senate bill to regulate animal experimentation in the District of Columbia. It is there that the Government laboratories are situated, so that the falsely called regulation would mean the prevention of scientific work; besides the passage of such a bill is acknowledged by antivivisectionists to be but the entering wedge to secure legislative enactment elsewhere. Hence our opposition to this particular effort of the Humane Association, and hence the request that every medical man use any influence he may possess on Senators to prevent the passage of the bill in question.

THE STATION-HOUSE VERSUS HOSPITAL.

ANOTHER one of those unfortunate cases which turn up every now and then, of a man suffering from some ailment that renders him unable to account for himself being locked up as drunk, has recently occurred in our city and is attracting a good deal of public attention. It happens that the person involved was of some prominence, being officially connected with the consulate of a foreign government. There is to be, it is said, a rigid investigation. A number of such cases we are sure happen each year and are glossed over in the police records without any call for investigation. We hope that the present case, by the publicity that will be given it, will do something to make the police more careful in the matter of committal to the station-house of supposed "drunks" who ought to be taken to a hospital as "dangerously ill."

There is scarcely a large city in the world in which each year there does not eventuate at least one case in which the neglect of the guardians of the peace in this matter may not be considered as directly responsible for the fatal termination of an illness or at least the serious jeopardy of life. In the present case it was said, on the part of the police, that even though there may have been cerebral hemorrhage or cocain intoxication the man certainly had taken liquor. Of the truth or falsity of this statement we know nothing, but it is certainly no justification for imprisonment during illness, that the patient is slightly under the influence of liquor. Indulgence in alcohol may have been the immediate cause of the condition that has developed, be it cerebral hemorrhage or diabetic coma or uremic symptoms, yet this constitutes no excuse for the patient's committal to a station-house when he ought to be taken to a hospital. Especially should it be insisted upon that the odor of alcohol on the breath must not be taken as a criterion as to whether the man is drunk or not. The taking of a certain amount of alcoholic beverages with meals has become too common in this country for any such eminently fallacious symptom to have any further weight.

This matter is extremely serious; it may easily involve human life. The problems it presents are likewise difficult. Experienced medical men have been deceived time and again into making a false diagnosis of alcoholic intoxication when something quite different was the matter, though there may have been the odor of alcohol about the patient. The certain differentiation often requires the highest diagnostic skill. Familiarity with conditions of intoxication on the part of the unskilled does not beget a special faculty for differentiating allied conditions, but rather superinduces a disregard for even striking pathological symptoms and a tendency to dispose of the cases summarily by putting them at once under the rubric, drunk.

The police must be thoroughly imbued therefore with the idea that the slightest suspicious symptoms in a case picked up on the street, where no explanation of circumstances is available, calls for medical examination. There can be no excuse for neglect of this important precaution. Police surgeons are ready at call, and a hospital ambulance with its surgeon may be had in a few minutes. At times this care would lead to useless trouble for the case would prove to be only a drunk after all. But it is infinitely better that such calls on medical skill should be made dozens of times needlessly than that one real sufferer should have to pass the night in the comfortless cells of a station-house.

ECHOES AND NEWS.

Gift to the Polyclinic.—A handsome oil painting of the the late Professor R. C. M. Page has been presented by his widow, Mrs. Page, to the New York Polyclinic.

Five Thousand Dollars for a Pathological Laboratory.—Dr. E. D. Morgan has given $5000 for the equipment of a pathological laboratory in the Bussey Institute at Harvard, of which Professor Theobald Smith is the director.

Deaths of Soldiers at Manila.—The last sanitary report from Manila states that during the previous week there had been only two deaths among the soldiers, one of typhoid

fever and one of cerebral hemorrhage, the result of an accidental fall.

Presentation to the New York Academy Library.—Dr. A. Jacobi has presented to the library of the Academy of Medicine for Dr. Voss of Germany a copy of the original edition of Gasparo Aselli's book "De Lactibus," a very rare bibliophilic treasure.

Professor Roentgen Goes to Leipzig.—Professor Röntgen, whose discovery of the X-ray brought him so much fame, has resigned his position as Professor of Physics at the University of Wurzburg to take the Chair of Physics at the University of Leipzig.

Defective Christian Science.—If Christian Science is a science at all, it should embrace not one but all divinely appointed means of healing, and for it to reject the remedies shown to be efficient by centuries of medical experience, savors more of self-conceit than it does of the humble faith which it claims as its merit.—New York *Sun*.

Another Medical Playwright.—Sir Thomas Grainger Stewart, former president of the British Medical Association, Professor of Medicine in the University of Edinburgh, and one of Her Majesty's physicians in Scotland, according to recent advices, has just completed a chronicle play, entitled "The Good Regent," which will be published shortly by Blackwood & Sons.

A New Test of Death.—The sensational subject of premature burial has been attracting considerable attention in Russia and Austria, where several cases have recently been reported, and the need of a scientific test of death has suggested the use of Röntgen-rays. The slightest movement of the heart blurs the skiagraph, and in Paris the X-rays have already been successfully used as a test of death.

A New Fad in Diet Reform.—The "Simian School" of Michigan tends very closely to strict vegetarianism. They grind nuts into various flours and meals, make combination foods of nut-meals and dried fruits, issue recipes in which the chief ingredients are nut-meal or flours, fruits fresh and dried, honey, sugar, milk, cream, butter, cheese, and buttermilk. Most of the followers object to meat as a food, but tolerate it when employed medicinally.

Recent Appointments in New York Hospitals.—Dr. Robert H. M. Dawbarn has been appointed visiting-surgeon to the City (Charity) Hospital. Dr. Thos. H. Manley has been reinstated as visiting-surgeon to the Harlem Hospital, and Dr. H. M. Silver has been reappointed to the visiting staff of Gouverneur Hospital. It has been reported, but upon how good authority we know not, that the last two appointments inaugurate the beginning of the establishment of the *statum quo ante*.

The Skin and Cancer Hospital.—At the recent annual meeting of the New York Skin and Cancer Hospital officers were elected for the ensuing year. Reports were received and read from the committees and departments of the hospital in relation to the work of last year. The year has been a notable one for the institution on account of the completion of its new building, at Nineteenth Street and Second Avenue, which has been built from the proceeds of the real estate formerly held by the hospital.

Corpse Fled from Coroner.—Coroner Apgar of Peekskill, N. Y., having been notified that a man was lying dead alongside the highway some five miles out of town, secured an undertaker, and with him drove out to the place where the corpse was said to be lying. In the meantime, the man who had been reported frozen to death had thawed out. When he showed signs of life and was told that the coroner and an undertaker were coming, he pulled himself together, "took a hitch in his belt," and left in a hurry.

To Check Tuberculosis.—There has been a great deal of talk recently of the need of some widespread action to cope with the increasing ravages of Great Britain's national disease, consumption. The Prince of Wales summoned a private meeting at Marlborough House December 20th to promote a war against tuberculosis. The Marquis of Salisbury and a number of famous medical men were present and participated in the proceedings. The spread of the gospel of cleanliness is a most excellent vocation for even the Prince. It is to be hoped that his efforts will take that direction.

Scientific Poisoning.—Sir James Crichton Browne, M.D., recently delivered an address on poisons and poison legislation before the Pharmaceutical Society of Great Britain, in which he pointed out that notwithstanding the remarkable progress of toxicology and the vast increase in the number and variety of deadly agents at the criminal's disposal, the poisoners of to-day, for the most part, use the same poisons as those by which murder was oftenest accomplished in olden times. Women and medical men, says Sir James, are the classes which have supplied the most numerous and most notorious poisoners.

Empress Loses Flesh and Health.—The Empress of Germany for some time has been using thyroid tablets as regular treatment for obesity. While she has succeeded in reducing her weight, she has been suffering seriously in general health, is becoming nervous, and is threatened with heart trouble. It is said that the Emperor, therefore, has induced her to stop using the remedy. The experience of the profession in this country emphasizes the opinion that thyroid extract is a serious heart depressant, that it should be prescribed with caution, carefully watched, and administered in conjunction with heart tonics.

Election of Officers of the New York Academy of Medicine.—At the meeting of the New York Academy of Medicine, held on Thursday, December 15th, the following officers were elected for the ensuing year: President, Wm. H. Thomson; vice-president, Hermann Knapp; trustee, E. G. Janeway; treasurer for the trustees, W. F. Cushman;

member of committee on admission, R. H. Sayre; member of committee on library, A. Caillé; delegates to the State Society, J. H. Huddleston, E. Lefevre, L. F. Bishop, J. A. Booth, James Ewing. Dr. Abraham Jacobi had withdrawn his name from nomination for the office of trustee.

The New Gas in the Air "Etherion."—The new gas which Mr. Charles F. Brush thinks he has discovered he has named etherion because it seems to possess some of the wonderful properties of the ether, which by hypothesis is the conducting agent through space of heat, light, and electric radiations. This is the fourth new substance, if the discovery is substantiated, found during the last few years to exist in the very air we breathe. It is the third new element that discoverers claim to have demonstrated in the atmosphere during the present year. This active awakening in inorganic chemistry can scarcely fail to have significant results for medical, especially physiological, chemistry.

The Antivaccination Law Criticised.—The new law enabling conscientious objectors to escape vaccination by making a statutory declaration has been availed of to exempt thousands of children from vaccination. Sir Richard Thorne, the principal medical officer to the Local Government Board, London, in his official report on vaccination during the last year, announces that one-third of the children in England and Wales have escaped vaccination. He predicts that the country is being prepared for widespread epidemics of smallpox, such as are unknown to the present generation. It is suggested, in order to counteract the antivaccinationists, that insurance companies refuse to issue policies to unvaccinated people.

Meeting of the New York Medical League.—On Friday evening, December 16th, the Manhattan Section of the New York Medical League met and discussed the subject "Midwives and Their Illegal Practices." W. A. Purrington, Esq., read a paper on "Some Legal Aspects of the Midwife Question." Mr. Elbridge T. Gerry's paper on "Midwives as Illegal Practitioners" was, owing to Mr. Gerry's illness, read for him. Dr. Theodore K. Tuthill read a paper on "Ways and Means of Dealing with the Illegal Practices of Midwives." A very interesting discussion followed. Owing to pressure on our columns this week we are unable to reproduce the abstract of the papers and discussion, but shall do so next week with editorial comment on the question.

Medical-Expert Evidence.—Justice John Woodward, in a paper on "Medical Expert Testimony," read before the one hundred and thirty-eighth meeting of the New York Society of Medical Jurisprudence, defended the present procedure. "A radical change," said the Justice, "is neither desirable nor possible. Every system of evidence must admit expert testimony, and all expert testimony is subject to human limitations. The medical profession must exalt the expert by investing in him as their representative all the dignity of his order. If he prove untrue to their confidence they should know what course to take to preserve their purity. The law, on the other hand, should invest the position with every safeguard, that the expert may not be influenced by bias, self-interest, or compulsion."

The Queen of Portugal; a Withdrawal and Apology.—The *British Medical Journal* confesses to having been the original publisher of the story that the queen of Portugal was studying medicine and that her first patient had been her husband, under treatment for obesity. The statements were formally contradicted by the Lord High Chamberlain of Portugal, and the Journal endeavored to set the matter right, but the story has been on its travels for some time. "There does not seem to be," quoth the editor of the *Journal*, "in the world of journalism, a bourne from which no traveler returns." We sympathize with the aggrieved editor, whose "bad pennies" come back to him thus inevitably despite his regret for their *utterance*. And as the MEDICAL NEWS has innocently been one of the guilty parties we make our humblest apologies to the Queen of Portugal and withdraw the story.

Contract-Surgeon in the United States Army. — For those seeking appointment the following requirements are exacted by the Board of Examiners: Evidence of graduation at a regular reputable medical college, diploma to be submitted to the board. Proof of hospital or other professional experience will be of benefit to the candidate. Candidates must be in good health, of reasonably sound physique, and citizens of the United States. The examination is of a practical nature, embracing hygiene, practice of medicine, pathology, and surgery. In addition, a thesis on some professional topic will be prepared by the candidate. The pay of acting assistant-surgeons is $150 monthly. The applicant must be free from physical defects which would incapaciate him from the military service. For further information address Major H. S. Kilbourne, surgeon, United States Army, Army Building, 39 Whitehall Street, New York City, President of Board of Examiners.

Dr. Archdall Reid on the Temperance Question.—Dr. Reid, in a pamphlet, assumes that inborn or congenital characters only are transmitted to the offspring, while acquired characters are not transmitted. Man is still undergoing evolution at the present day, and this consists in the main of acquiring immunity against disease or the effect of powerful drugs, including harmful narcotics. Man is being evolved in the direction of decreasing his normal craving for alcohol. In proof of this theory, Dr. Reid states that where wine is most plentiful, as in Southern Europe, there is less drunkenness than in countries where acoholic stimulants are more difficult to obtain. The novel view is advanced that anything that tends to restrict the supply of alcoholic beverages will tend toward perpetuating drunkenness. The innate drunkard, when discovered by allowing every one free access to alcohol, must be treated as a lunatic, and not allowed to procreate. By artificial selection, then, the alcohol-tainted "germ-plasm" will finally be eliminated, and we will see the human race entirely immune to alcohol.

A Correction.—In making our announcement last week in reference to the articles on garrisoning the tropics, we stated that Dr. Azel Ames was going out to Puerto Rico as chief medical officer on the staff of General Henry. This was an error. Dr. Ames writes: "In the performance of my duty I shall be a plain acting assistant-surgeon of the United States Army under the orders of the chief surgeon of the department, Lieutenant-Colonel John Van R. Hoff, surgeon United States Volunteers (major and surgeon United States Army), who not only most ably fills the position, but is a competent sanitarian under whom it is a pleasure to serve. . . . To the cordial and highly intelligent support given at all times by General Henry to sanitary work, and the competent supervision and cooperation of the chief surgeon, the greater part of such results as have been achieved with the army and people of Puerto Rico in sanitary affairs has been due, as it must be for the future." Dr. Ames was formerly Sanitary Inspector in the Department of Ponce. His field of operation will now embrace the entire island.

A New Official Position for Doctors.—One of the contestants in a recent prize-fight in England died shortly after receiving a blow on the chest. The fighting had not been severe and the blow was not such a one as in experts' minds was calculated to do serious harm. Moreover post-mortem examination disclosed the existence of an extremely small heart. The jury brought in a verdict of accidental death but with the "rider" that in future boxing contests the contestants' conditions should be carefully examined and their fitness certified to before the contest be allowed to take place. This will constitute a new set of duties for physicians for which a certain amount of special training may be required. Some time ago in France a book appeared on the etiquette to be observed by the surgeon called in attendance on a duel. If the English Coroner's jury's recommendation prove effective, we may look for pamphlets and manuals on "the proper conduct of the physician when called to attend an exhibition of the manly art." May we add that one of the indispensable qualifications will not be to be an expert in aphasia.

Climate and Conditions in Manila.—The following from an American naval officer who visited the Philippines shortly before the breaking out of the recent war will be of special interest now that it is definitely settled that the islands are to be ours. It gives in brief a good notion of how different the conditions are there from what obtains here, and how promptly intending settlers will have to change their ideas as to business hours if they are to retain their health during their residence in the tropics: "The climate of the islands is healthy but hot. The maximum range of the thermometer is 103° F., but a sea breeze usually sets in about 5 P.M. and lowers the temperature. The greatest annual rainfall recorded is 114 inches, the least 84. There are 323 Europeans and Americans, 4506 Spaniards, 16,520 Chinese, 47,662 Chinese Mestizos (half-breeds), 4963 Spanish Mestizos, and 200,966 pure natives in Manila. The population seems to be divided into the clergy, the officials, the half-breeds, and the native Indians. The business hours are from 5 to 9 in the morning and from 5 P. M. to midnight. The middle of the day is devoted to quiet lounging and sleep." —"An American Cruiser in the East," by John D. Ford, 1st Engineer of the Pacific Station, U. S. N.

This Is Not the Stuff of Which Martyrs Are Made.—Mrs. Eddy, the "mother" of the Christian-Science Church, has written a letter to the New York *Sun* which concludes as follows: "To be stoned for that which our Master sought to designate His best works, saying, 'For which of these works do ye stone me?' is thereby to make known the best work of Christian Science." Let us see how likely Mrs. Eddy is to wear the martyr's crown. She is engaged in the business of selling a book which has now passed its 153d edition. The price of this book is $3 ($3.18 by mail); this book can be put on the book-store shelf at a cost of less than forty cents. She also sells a number of other works at proportionate rates. For many years she ran a "metaphysical" college, and her students paid well for the privilege of learning how they could in their turn profit by the propagation of Christian Science. She preaches the unChrist-like doctrine that "no one has any business to be poor." She communicates with the outer world through her "counsel, Judge So-and-so," etc. And Mrs. Eddy claims to be a disciple of Jesus Christ! What an excessively malodorous business it is, and how repugnant to people of true religious instinct.

The Plague in Samarkand, Russia.—Prince Alexander, who went out to Samarkand by order of the Czar, as president of the commission appointed to take measures against the bubonic plague, reports that he found in the village of Anzob, where the plague was raging, a hospital had been established and proper quarantine regulations inaugurated. The local doctors have pronounced the disease bubonic plague. To prevent the further extension of the plague three lines of medical stations have been established on the various routes leading from the infected town. Flying medical military detachments supervise these stations, as well as the whole of the surrounding districts. In anticipation of the possible spread of the disease, reserves of doctors and nurses are being summoned in the principal cities of the empire, who must be ready to go at a moment's notice. At present these reserves consist of 100 doctors and 80 nurses. All the means for inoculation according to Jersen's system are supplied in abundance; also the remedies of Kharkin are being prepared in the Imperial Institute of Experimental Medicine at St. Petersburg. The doctors have been instructed to use these and to publish them among the population. Of the 357 inhabitants of Anzob, 233 have died. Since October 22d there have been no new cases. There are in all fourteen cases at present.

An English Medical Hero.—The Victoria Cross has been recently conferred upon Surgeon William Job Maillard, M.D., of the Royal English Navy, for conspicuous bravery during the outbreak at Candia, on September 6, 1898. The act of courage for which he was recommended for

this highest and most exclusive distinction for bravery in the world was as follows: During the landing of seamen from Her Majesty's ship "Hazard" Surgeon Maillard, who had disembarked and reached a place of safety, returned through a perfect deluge of bullets to the boat and endeavored to bring into safety, Arthur Stroud, ordinary seaman, who had fallen back, wounded, into the boat, as the other men jumped ashore. Surgeon Maillard failed to bring Stroud in only through the boat being adrift, and it being beyond his strength to lift the man (who was almost dead) from off so unstable a platform. Surgeon Maillard returned to his post with his clothes riddled with bullets, though he, himself, was unhurt. Such are the glorious deeds, and they are not few in number, that have finally won from the military authorities of England that recognition for the Army medical corps that it deserves. Until recent reforms the men who did them were sneered at as non-combatants and superciliously considered not to be equals of the men who did the fighting.

A Second Death from Hydrophobia.—We reported some weeks ago the death of August Bombadi of Astoria, aged five years, from what was supposed to be hydrophobia. We now have to report another, that of Otto Quast, aged five. Both cases occurred in children too young to have been frightened into hysterical convulsions in the midst of which some intercurrent affection might carry them off, so that the ordinary explanation given for American hydrophobia cases in these instances falls to the ground. The little Bombadi had not been specifically treated. Otto Quast had been under treatment at the Pasteur Institute of New York, but the bite was on the cheek and the prognosis of head bites being very unfavorable even with prompt treatment, the parents had been told that the treatment was not sure to prevent the development of the disease. Three other persons, two children, respectively four and eight years of age, and a young man of seventeen, were bitten during the same day as these children, October 19th, in the same neighborhood and presumably by the same animal. Young Quast's father had also been bitten quite severely, but on the hand, by the large brown dog that had attacked his son. The wounds of all four of these are on the arms and hands, which are not so dangerous. They promptly underwent the Pasteur treatment so that further fatal results are not to be feared. The series of cases is an extremely interesting one, however, and we shall endeavor to secure further details of them so as to make them available for thoroughly scientific medical criticism.

SPECIAL ARTICLE.

BACILLARY CONTAMINATION OF OYSTERS.

THE third and final report of the Committee of the British Association for the Advancement of Science appointed to report on the "Elucidation of the Life Conditions of the Oyster under Normal and Abnormal Environment, Including the Effect of Sewage Matters and Pathogenic Organisms," has been drawn up and presented by Professor Herdman, Professor Boyce, and Dr. Kohn.

In nine out of nineteen samples of oysters examined a colon-like bacillus was isolated from the interior of the oysters. In some samples there was almost a pure culture of the colon bacillus. Careful investigation shows that some of the organisms in the colon-bacillus groups thus isolated are much more closely related to the bacillus of typhoid fever than are others. For instance, while the typical colon bacilli coagulate milk, form indol and gas, and give a decided acid reaction as well as an abundant growth upon potato, groups of the bacilli were isolated which did not exhibit all of these qualities. Indeed, one group of very active bacilli did not coagulate milk nor form indol, though occasionally forming gas, and gave rise to an acid reaction in two cases, and an alkaline reaction in three cases. This group of colon bacilli and some of the others in a less degree were suspiciously like typhoid bacilli, but the serum reaction, carefully tried, always gave negative results so that it was not the true typhoid bacillus.

The presence of the colon bacillus and its congeners usually means sewage contamination. A previous report of this committee has shown that oysters kept in water into which sewage drained contained many more microorganisms than those of the same variety kept only a short distance away in pure water, and that oysters were able to make use of sewage as food material.

There is evidently, therefore, need of regulation in the matter of oyster growing. The committee recommend either that restrictive legislation be called in and oyster-beds be licensed only after due inspection by Government officials, or that an association be formed among oyster-growers and dealers themselves, which shall provide for the due periodic examination of the grounds, stores, and stocks by independent, properly qualified, inspectors. The commission is of the opinion that the scientific assistance and advice given by such independent inspectors would go far to improve the condition of the oyster-beds and layings, to reassure the public and to elevate the oyster industry to the important position which it should occupy. The concluding recommendation is that other forms of shell-fish, and the grounds from which they are gathered, should be periodically examined by scientific inspectors in the same manner as the oyster-beds, precautions being just as needful, perhaps more so, for these as for the oysters.

CORRESPONDENCE.

THE COLOR OF NEGRO BABIES.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—The editorial in the MEDICAL NEWS December 10th, entitled "The *Lancet* and the Color of Newly Born Negro Children" recalls an incident which occurred at a lecture on obstetrics at the College of Physicians and Surgeons, New York, a few years ago.

Professor J. W. McLane had brought a newly born colored child, a day or two old, into the lecture-room to illustrate his remarks on the subject of the lecture. The

child's color was anything but black or white, but it approached most closely to a dark salmon color.

The professor held the piccaninny at arm's length and in his peculiarly delightful manner asked the class what the baby's color was. Some said white, while others said black. To both of these responses the witty professor shook his head in the negative and in true Irish fashion, remarked, "It's nather; its red."

Dr. McLane then added that as a rule piccaninnies were red at birth while white children were gray.

Very respectfully,

A. L. WOLBARST, M.D.

NEW YORK, December 17, 1898.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—The color of a newly born negro child is what we term a light "ginger-cake" color. This light color prevails, as a rule, even if both parents are typical blacks, almost as much so as when mixed with a large percentage of white blood. There are a variety of shades from the darker to very light, almost indistinguishable from the color of a child of white parents. I have never seen a newly born negro child black; though a few are dark they are always lighter than their parents. Often it would be a difficult matter to decide whether the child was of white or negro origin unless the parents were known. My attention has frequently been directed to their color, so much so as to cause me to ask if the child did not have a white father.

On examination, generally, small areas of darker or almost black skin will be found, especially about the genital organs, if a male, and around the anus. The prepuce is generally very dark or black.

D. M. PROVENCE, M.D.

BARWELL, S. C., December 15, 1898.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—To relieve the perplexity of the *Lancet*, and in the interest of accurate observation of minor points in practice I shall proceed to state the color of a new-born full-blooded negro baby. I have delivered a score or more of the little problems this year and speak from ocular demonstration. A new-born full-blooded negro baby is neither white nor yet is it black but is of a dusky red color. In some, though not all, the scrotal integument and that about the flexures of the principal joints is black at birth, but the general surface is of a dusky red.

Respectfully,

C. J. MARCH, M.D.

FORDYCE, ARK., December 12, 1898.

HARVARD NOT THE PIONEER.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—In the issue of the MEDICAL NEWS for December 10th occurs the following sentence with regard to the building of an infirmary for Harvard: "Harvard is to be congratulated on being a pioneer in this as in so many other things that tend to make student life more livable." If in the place of *Harvard* you put *Cornell* you will be correct. Last year Dean and William Sage gave to Cornell University the mansion of their late father, as a memorial to him, to be used as an infirmary; and they not only fitted it up and equipped it for that purpose but for its perpetual maintenance they presented with it an endowment of $100,000. A description of this building may be found on pages 56-58 of the Annual Report of the President of Cornell University for 1897–98.

Respectfully,

W. I. HOAG, M.D.

INDIANAPOLIS, IND., December 12, 1898.

[Honor to whom honor is due. Cornell University is evidently the pioneer in this beneficent work.—ED.]

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent.]

AN INFLUENZA EPIDEMIC—SMALLPOX IN PENNSYLVANIA—CONTAGION AND INFECTION—BOTTINI'S OPERATION—DISSECTING ANEURISM—THE WIDAL REACTION—FREE HOSPITAL FOR CONSUMPTIVES—CHARITY BEQUESTS—PERSONAL NOTES—HEALTH STATISTICS.

PHILADELPHIA, December 20, 1898.

WHILE we have been accustomed, ever since the epidemic of 1889, to call any severe "cold" a case of the grippe, there is now a genuine epidemic of influenza in this city. It seems to be of a mild type, but the rapidity with which it is spreading makes it seem likely to prove quite a factor in the list of winter affections this year.

Smallpox has broken out at Bedford and Huntingdon, about thirty cases having been reported thus far. General vaccination and house quarantine have been ordered by the State Board of Health which, it is hoped, will check the epidemic.

At the same meeting Dr. Lawrence F. Flick, in a paper, entitled "Contagion; Its Meaning and Limitations," attempted to define the exact difference between the words "infection" and "contagion." He believes the key to a distinct understanding lies in going back to the original definite use of the words, thus including the greater number of diseases under the first head. Contagion, according to Dr. Flick, should be applied to those diseases which are transmitted without the aid of an intermediate host, an unbroken chain, while infection must entail the lodgment of the organism in an intermediate host. He also made a division of diseases under these headings, though he admitted that this was difficult, if not impossible.

Dr. Augustus A. Eshner, in the discussion, took an opposite view believing that "contagion" should be restricted to disease spread by actual contact and, further, he classified the parasitic skin and intestinal diseases as "invasion diseases." Dr. Solomon Solis-Cohen also disagreed with Dr. Flick, and probably expressed the views of most medical men when he said that he favored classifying diseases as "infectious," with a subdivision of some as "contagious."

Dr. A. Feree Witmer read a paper on "Aphasia from an Unusual Cause," and exhibited the patient, a young boy, whose symptoms had come on after an epileptic convulsion. Paraplegia had been present also and the case

seemed to have clearly been caused by a cerebral hemorrhage occurring during an epileptic attack.

A report on "Bottini's Operation for Enlargement of the Prostate Gland; Exhibition of Instrument" was presented by Dr. A. J. Downes. The operation was performed with Freudenberg's modification of Bottini's instrument, which consists of a hollow bougie in which a cautery-knife, having electrical attachments, is concealed and through which a continuous stream of ice-water flows to keep the instrument cool. After introduction, the blade, which has been heated to a cherry red, makes the desired number of incisions, hemorrhage being almost *nil*. Dr. Downes introduced half an ounce of a four-per-cent. cocain solution into the urethra, preferring to use this large amount and washing the excess away rather than to allow a less amount to remain. His case was most successful.

At a meeting of the College of Physicians, held December 12th, Dr. Judson Daland reported a case of "Dissecting Aneurism of the Thoracic Aorta," occurring in a male, aged thirty-eight years, who gave a clear history of alcoholism. The aneurism had caused death finally by rupturing into the pericardium. During the time the patient was under observation, he had presented symptoms of mitral regurgitation, arteriocapillary fibrosis, and chronic nephritis.

Most favorable results were reported by Drs. Sailer, Campbell, and Grissinger, with the Widal reaction. A wet method, by using a Thoma-Zeiss pipette, was found preferable to the dry and, Dr. Sailer believes, is much more reliable. In the discussion Drs. Scott and Daland said they had seen cases of various other infections in which an equally positive and erroneous reaction had been yielded. Drs. Osler, Stengel, and Eshner spoke of the occasional delayed appearance of the reaction.

The Philapatrian Ball, which is to be held February 13th, will be for the benefit of the Free Hospital for Consumptives. Dr. Lawrence F. Flick, President of the Pennsylvania Society for the Prevention of Tuberculosis, is also president of this hospital, which was organized in 1895. The hospital devotes all money received to placing patients in already existing institutions thus saving the expense of erecting buildings. Philadelphia, including its almshouse, has only about 200 beds for this unfortunate class of people, most hospitals refusing to take cases, and the amount of good accomplished by the Free Hospital can hardly be overestimated.

By the will of Eliza W. S. P. Field, who died in England about a year ago leaving the bulk of her estate to charity, the following bequests to institutions in this city were made: Home for the Incurables, $10,000; Germantown Hospital and Dispensary, $500; Children's Hospital, $1000; University of Pennsylvania, for two scholarships, $10,000; for a free bed to be known as the John White Field bed, $5000; the Abbey Willing Peters bed, $5000, and for the Hospital, $20,000. The Maternity of the University receives $10,000 also, and for general purposes $10,000 more is given.

Dr. M. S. French, Secretary of the National Relief Committee, has left for the South to visit the various camps, and Major D. C. Peyton, who has charge of the Government hospital work in Philadelphia, has gone to his home in Indiana on leave of absence for two weeks.

Dr. J. J. Gurney Williams, senior resident-physician of the Episcopal Hospital, was extensively burned while using the X-ray apparatus last week. The burned surface resembled that from ivy poisoning, and while not severe, was exceedingly painful.

Dr. John Lindsay, Secretary of the Philadelphia County Medical Society, is severely ill with pulmonary tuberculosis.

Dr. S. Weir Mitchell sailed for Europe last week on the "Kaiser Wilhelm."

Dr. Leonard Pearson, State Veterinarian, has gone to Pittsburg to investigate an outbreak of hydrophobia. Dr. Benjamin Feicht died last week after having been bitten by a rabid dog and since then there have been two other victims.

The total number of deaths occurring in Philadelphia during the week ending December 17th, as reported at the Health Office, was 481, of which 118 occurred in children under five years of age. The total number of new cases of contagious diseases was 313, reported as follows: Diphtheria, 103 cases, with 28 deaths; scarlet fever, 32 cases, with 1 death; typhoid fever, 178 cases, with 16 deaths.

OUR LONDON LETTER.

[From Our Special Correspondent.]

POPULAR CLASSES AT THE MEDICAL MUSEUM OF THE ROYAL COLLEGE — THE STUDY OF TROPICAL DISEASES — SURGEON MAILLARD HONORED WITH THE VICTORIA CROSS — ELIMINATION OF THE SMOKE NUISANCE IN LONDON—RIDER HAGGARD'S "DR. THERNE" — FURTHER DEVELOPMENTS IN CONNECTION WITH THE ABORTIONIST BLACKMAIL SCHEME.

LONDON, December 15, 1898.

A DEPARTURE well worthy of imitation in the utilization of our medical museums in America may be seen here on Saturday afternoons. Every alternate Saturday half-holiday the Curator of the Museum of the Royal College of Surgeons devotes an hour and a half of his valuable time to taking classes of school-teachers, workingmen's clubs, and students of night-classes through the superb anatomic and physiologic galleries of the museum. The principal objects and specimens of interest are pointed out and a charming, popular lecture with demonstrations is made out of them. The parties often number forty or fifty persons, and the interest manifested is of the keenest. On certain afternoons of the week the normal rooms of the great osteologic collection of John Hunter are open to teachers and students in science classes, and those from the National "extension" school of science which has its headquarters at South Kensington are permitted quite extensive privileges in "getting themselves up" for examination in the spring.

The laity are becoming eager for enlightenment upon both physiology and pathology and we shall wrong our profession if we do not supply it freely, instead of leav-

ing it to the "treatises," "mothers' friends," and "confidential advice," of Warner, Pierce, Hostetter, *et al.*

The idea of the hospital for the study of tropical diseases seems to be almost as infectious as the maladies it is to have care of. Several of the London schools have intimated that they are prepared to offer all the facilities required in that line by colonial physicians, and now Liverpool announces similar intentions. Mr. Alfred Jones has offered the sum of $1750 a year for a term of years for the laboratory, and the Royal South Hospital is to furnish a ward for the cases. There ought to be no lack of material in Liverpool.

There appears to be some professional dissatisfaction with the methods of the Government in establishing the new School of Tropical Medicine. The present staff of the hospital utilized have issued a protest based upon the statement that they were not properly consulted before the departure was announced and their names published as teachers. On the other hand, certain medical colleges seem to be jealous of the honors thrust upon this small and little known hospital. We sincerely trust that the proverbial "differing" of doctors will not be exhibited in public and so hamper the scheme.

The Bradshaw Lecture was given this week at the Royal College of Surgeons by T. Pickering Pick upon "The Union of Wounds." He absolutely declined to limit the term "inflammation" to septic processes due to the presence of micro-organisms as proposed by Park and Roser, and took the position that every one of the five "methods" of wound-healing is due to inflammatory processes of greater or less intensity. This of course brought him face to face with the question whether this inflammation is really a pathologic process, which the lecturer after careful discussion decided in the affirmative. It is a "reaction of degeneration," a reversion of the cells to an embryonic type of reproduction and product, and results in the ultimate substitution of a lower form of tissue. Scar-tissue, although functionally physiologic is structurally and developmentally pathologic.

The "heroes of peace," or at least of peaceful occupations are getting their share even of official recognition at last. Queen Victoria has decided to confer the Victoria Cross upon Surgeon Maillard of the Royal Navy, for distinguished bravery during the recent attack by the British iron-clads upon Crete. While the troops were being landed one of the sailors was wounded and fell back into the boat while the other men rushed on shore. Dr. Maillard who had reached a place of safety promptly dashed back through a perfect hailstorm of bullets to try to bring his patient into shelter. The man, however, was found to be in a dying condition and was too heavy for the brave surgeon to lift out of the drifting boat, so that he was obliged to leave him and return to his post. His clothing was cut to ribbons by the bullets, but he himself by a miracle escaped unhurt.

The military authorities seem to have profited by the storm of censure which their pig-headed refusal to grant a similar decoration to the surgeon of the Gordon Highlanders for similar heroism at Dargai, simply because he was a *civilian*.

A vigorous crusade has at last been set on foot against the smoke-fog nuisance in London. Sir Henry Richmond has organized a determined onslaught upon the vestries or parish councils to compel the enforcement of existing laws which rigidly limit the amount of black smoke permitted to be poured out by factories. Experts declare that by proper stoking and arrangement of flues to draw the smoke back through the furnace before permitting it to escape, black smoke can be absolutely done away with and with postitive economy of fuel. The only obstacles are the carelessness of the men and the short-sighted stinginess of the owners. If this triumph could be achieved it would add greatly not merely to the comfort but also to the healthfulness of London in winter. One day of fog is depressing but two or three of it in succession sends up the mortality bills at once, not by respiratory diseases as is usually supposed by every one who has swallowed the reeking, woolly, vapor, but in all sorts of wasting diseases for the depression of vitality due to the absence of sunlight. The same effect may be noted upon our involuntary citizens, the animals at the Zoo; a black fog sends up their death-rate worse than the severest storm or the sharpest frost.

The verdict in the Harold Frederic case was about what was expected. The prosecution, at the close of the evidence, asked the court to dismiss the case against Miss Lyon who, though deluded, they believed to have been sincerely devoted to the deceased, and the Judge acceded and included Mrs. Mills, the "healer," on the ground of insufficient evidence. This really seems the wisest course for it was clearly shown that Harold Frederic though erratic, was fully competent to decide upon what form of treatment he preferred and had done so deliberately. In fact, we have the best of authority for the statement that he really had no confidence whatever in either Christian Science or rational medicine, and chose the former simply because it interfered least with Nature and his own preference. Doctors took away his beer and cigars and kept him in bed, upon some absurd theory about vegetations upon his valves; Mrs. Mills told him he had neither vegetations nor valves and could do just as he pleased. So he chose her as a medical adviser—and died suddenly. In the language of the prairies, "Whose funeral is it?"

We certainly are coming to the front as a profession. After consistently abusing us for centuries—mainly because we richly deserved it—literature has actually begun to mention us with approval and even champion our causes. A most unexpected and efficient ally in our campaign against smallpox has just appeared in the form of a novel by no less a writer than Rider Haggard. "Dr. Therne" is a brilliant and skilful *expose* of the antivaccination crusade and its demagogic methods, in which the hero is a leader, and culminates in a masterly description of the fearful epidemic which devastates England, when after twenty years of the "conscience-clause" vaccination has become obsolete. It is a fascinating story as well, and aught to be "a Douglass in the field" for our side—if the "antis" ever read anything except their own lying pamphlets.

A singular "baby-powder" has just been reported from

the town of Blackburn. A physician was called to see a child aged four weeks which he found in a severe attack of colic. Pain had already persisted some days, and upon looking into the mouth he detected a distinct blue line upon the gums. The most careful search and questioning failed to discover any source of lead until he happened to take up a paper of dusting-powder which lay upon the mantel and found written upon it, to his horror, "Powdered White Lead." The nurse, an experienced (!) woman, had been told this was excellent for babies' skins, and purchased it at a drug-store! The nipple of the feeding-bottle was found resting upon the paper. The child recovered, although perhaps its skin is not as brilliant as if the complexion-powder had been continued.

Two cases of the fascinating African "sleeping-sickness" are now in the Seaman's Hospital, both being in Congo natives—a man of twenty-two, and a boy of eleven. Both began to be drowsy in May last, falling asleep over their work, and even over their meals, and the lethargy has gradually deepened until they now sleep all day long, but can be awakened to swallow food. The man can be roused to answer questions but the boy is almost unconscious. This remarkable disease has a latent period of from three to seven years after infection, and a chronic course of from six to fifteen months, but is invariably fatal. It will depopulate whole villages, ploughing through the population at the rate of fifteen to twenty per cent. per annum, until half are dead and the remainder fleeing in terror. No case has ever originated outside of a certain zone upon the west coast of Africa, but in the days of the slave trade negroes would sicken and die of it years after they had been brought to the West Indies.

The abortionist blackmail scheme of "C. J. Mitchell" proves even more gorgeous than was at first suspected. The affair was engineered by three brothers of the suggestive name of Chrimes who not only sent the "official" letters threatening prosecution, but had previously advertised and sold the remedy to their unsuspecting victims, thus securing double profits. From the overwhelming nature of the evidence against them it looks as if they might secure a third and unexpected one. The attitude of the press is being aired in the most edifying manner. Publishers can no longer plead ignorance or oversight for it has been shown in this trial that their rates for such advertisements are double, treble, and even quintuple the ordinary rate. Most useful of all, the case has drawn from the police authorities the public notice that in future all newspapers inserting such advertisements after one warning, will render themselves liable to prosecution for inciting to crime!

What won't the antivivisectionist make capital out of? A public meeting has just been held in London for the purpose of calling attention to the fearful danger to which the community is being exposed by soulless doctors, as illustrated by the outbreak of the plague at Vienna, the "bearing of which observation" as Captain Cuttle remarks, being explained when a resolution was introduced protesting against public money being used to establish a central bacteriological laboratory for London. It was casually remarked that of course men whose finer feelings had been utterly blunted by inflicting agonies upon dumb guinea-pigs, could not be expected to reck in the least what risks their experiments with the virus of deadly diseases exposed the public to!

CONGENITAL STENOSIS OF THE PYLORUS—CANCER OF THE LARGE INTESTINE—CHANGE IN THE TYPE OF TYPHOID FEVER IN THE LAST FORTY YEARS—SEQUELÆ OF INFLUENZA—VASCULAR MURMUR OF OBSCURE ORIGIN—SARCOMA AND COLEY'S FLUID—RARE CASE OF MULTIPLE DERMOIDS—HYPERPYREXIA—A RABBIT'S FEMUR USED TO SUPPLANT AN ULNA — CANCER OF THE WHOLE INTESTINAL TRACT—DANGERS OF IMPURE ANESTHETICS.

AT a meeting of the Royal Medical and Chirurgical Society, November 8th, CAUTLEY read a paper on "Congenital Hypertrophic Stenosis of the Pylorus," a condition of importance in its relation to hypertrophy of adults, as well as in its immediate effect on the life of the infant. Since 1841 some twenty undoubted cases of this condition have been reported. The child was usually fine looking at birth, but characteristic symptoms soon made their appearance. Such were: (1) Vomiting, occurring without apparent cause, and persisting in spite of treatment; (2) the absence of bile from the vomited matter; (3) obstinate constipation; (4) marasmus; (5) the presence of a tumor in the region of the pylorus; (6) the absence of abdominal distention except from dilatation of the stomach itself in some instances; and (7) the absence of signs or symptoms of gastritis, and of the more common forms of intestinal obstruction. The influence of inherited disease, family predisposition, and sex were apparently unimportant. Pathologic specimens were shown. In each case the pylorus was about the size of the last phalanx of the little finger. The hypertrophy of the muscular layer threw the mucous membrane into longitudinal folds. In two cases a tumor had been made out during life. If this can be done surgery may be tried, otherwise palliative measures are indicated. It was suggested that the thickening was of a redundant character, Nature, in her attempt to provide a sphincter, rather overdoing the matter. Thompson suggested that it was due to spasm set up by swallowed amniotic fluid, but there was no evidence that spasm of the pylorus can produce hypertrophy.

At the Harveian Society, November 3d, BATTLE read the notes of "Three Cases of Malignant Disease of the Large Bowel," in each of which he had operated for obstruction, with perfect success. In one patient, a man aged forty-four years, with more or less obstruction for three years, there was an intussusception palpable in the rectum, near the apex of which the growth was found to be situated. In this patient, and in a woman aged twenty-nine years, suffering from a growth in the descending colon, colostomy was performed, and the tumor was removed some weeks later. In the third patient, a woman aged forty-five years, the tumor of the sigmoid flexure was removed at the first operation, the

ends of the bowel were brought out in the wound and stitched, and the septum between them was gradually cut away during the following days by means of clamp forceps. The advantages of "short-circuiting" and lateral anastomosis were pointed out, and the speaker said that colotomy ought to become a rare operation if patients are brought in during the early stage of the disease.

PHILLIPS said that typhoid fever has essentially changed its type during the last 'forty' years. Formerly diarrhea occurred in ninety-six per cent. of the cases, but now it is found in only fifty per cent. The lessened severity of abdominal symptoms coincides with the lessened severity of the intestinal lesions, and now it is not uncommon not to find ulceration even at autopsy. Fifty per cent. or more of the deaths at present are due to toxemia, pyrexia, heart-failure, or asthenia. It is necessary to keep up failing cardiac power by tonics, food, and diffusible stimulants. Diarrhea should be controlled by enemas rather than by drugs given by the mouth. Hamamelis is often serviceable in stopping hemorrhage. If perforation occurs immediate surgical assistance should be summoned.

BROADBENT advocated the wider application of the cold bath, as its use on the Continent and in America has undoubtedly done much to diminish the percentage of fatal cases.

At the Bradford Medico-Chirurgical Society, October 25th, KERR showed two patients, mother and son, suffering from a disseminated lesion of the central nervous system, probably toxic in origin, and following attacks of influenza. In each case there was delayed convalescence, followed by failure of sight and power of walking. There was incoordination of muscular movements and difficulty in micturition. The knee-jerks were exaggerated. The patients remained bright mentally, but were inclined to be too emotional. They had suffered from influenza at the same time, seven years ago.

At the Medical Society of London, November 14th, MACKENZIE showed a case of vascular murmur of obscure origin audible at the base of the right lung. The man had been under treatment for four years for tuberculosis, with slight hemoptyses. There was diminished resonance, bronchial breathing, pectoriloquy, and crepitant râles at the apex on the right side. Otherwise the lungs were apparently normal. At the base of the right lung was heard a loud blowing murmur, occupying nearly the whole of the cardiac cycle. The murmur resembled in character that sometimes heard over an aneurism when an artery and vein communicate. The position of maximum intensity was situated over the seventh, eighth, and ninth ribs in the posterior axillary line. The murmur was not much affected by respiration. From its situation it was unlikely that it was due to an aneurism. Perhaps it was caused by an angiomatous growth in the lung or in the liver.

CALEY suggested that it might be caused by a constriction of the vena cava where it passed through the diaphragm.

BATTLE showed a man who had had tumors in the neck, anteriorly and posteriorly, over the sternum and in both axillæ. Microscopic examination had been made, and the clinical diagnosis of sarcoma confirmed. The patient had taken iodid up to 25 grains three times a day without any good result. He was then treated with Coley's fluid, in half minim and minim doses, for a period of three months, and the tumors entirely disappeared. They were of the spindle-celled variety of sarcoma.

OWEN said the diagnosis of sarcoma did not appear to be certain, and he thought the examination of specimens removed from the living subject are apt to mislead. If it were a sarcoma, why were the glands in the axilla enlarged? It would be very unlikely that a sarcoma of the breast or in its neighborhood would infect the axillary glands. He suggested that it might be a case of granuloma of syphilitic or tuberculous origin.

MOULLIN said that he had examined the tumors and the microscopic sections, and could not conceive that the growth could be anything but sarcoma. He had seen two abdominal tumors disappear under this method of treatment, and while he believed them to be sarcomata, he could not state so absolutely, as no microscopic examination had been made.

OWEN expressed himself as sceptical regarding the diagnosis of sarcoma in such cases. He had seen one subject treated by Coley's fluid for malignant disease of the end of the femur. Later the patient passed into another hospital, and excision of the hip was performed, and the trouble turned out to be tubercular. If this patient had recovered the case would have been set down as a cure by Coley's fluid.

WATERHOUSE had seen the remedy applied in five cases of inoperable sarcoma. Three of the patients suffered from rigors after its administration, and two of them died with hyperpyrexia after moderate doses. In no one of these five cases was there any apparent benefit. Another man had what was considered to be sarcoma of the lower end of the femur. Sections of the tumor were taken and examined in both England and Germany. The pathologists agreed that the growth was a round-celled sarcoma. Some months later suppuration occurred and a piece of necrosed bone came away. The patient recovered without the use of Coley's fluid.

At the Pathological Society, November 15th, LATHAM showed specimens of multiple dermoids found in the abdomen of a woman who had died from peritonitis, set up by the perforation of a dermoid of the ovary. There was one large one attached to the stomach, and many small ones in connection with the stomach, descending colon, and suprarenals. Such a multiple occurrence of dermoids is very rare, and has been attributed by some to malignancy. The speaker, however, inclined to a theory of transplantation.

At a meeting of the Clinical Society, November 11th, MARSH read a paper on "Primary Sarcoma of the Synovial Membrane of the Knee-joint." In September, 1892, he removed from the synovial membrane of the left knee of a man aged twenty-one years, a growth the size of a small tangerine orange. Microscopically it was a mixed spindle- and round-celled sarcoma. The tumor had been in existence for fourteen months. During the next five years recurrences were four times removed. In each in-

stance the disease was confined to the synovial membrane. In December, 1897, a recurrence presented itself posteriorly, and as the knee-joint was pretty nearly useless, amputation was performed. This recurrence, like the others, was confined to the synovial and subsynovial tissues. The disease had not reappeared up to the time of the report.

PITT reported a case of hyperpyrexia in a neurotic woman with bronchiectasis. The patient, twenty-six years old, had suffered four years from attacks of hemoptysis and abundant expectoration of a non-tubercular type. There was marked bronchiectasis and periods of dyspnea lasting for two or three days were of frequent occurrence. In these attacks her temperature in the left axilla was two to four degrees higher than that in the right. At times her temperature on the left side was 114° F., or even higher. The rectal temperature was not extreme. The dyspnea was so great that her temperature could not be taken in the mouth. Prostration was extreme and the pulse was frequently as high as 140. From time to time the patient broke out in a profuse general perspiration. The urine was scanty during an attack, but it never contained any albumin. No explanation was offered for the unusual temperatures, but there could be no doubt that they were genuine, as they were taken every four hours during a period of many weeks, by several different persons, using different thermometers. The patient was so prostrated that she took no notice of the temperature record and any supposition that she raised the mercury by friction on the thermometer would have been ridiculous. In *Guy's Hospital Reports* for 1893 Bryant published extracts of 100 cases of hyperpyrexia. Physiologists have been unable to give the cause of such high temperatures, in one instance up to 128° F.; but there is no reasonable doubt of their occurrence.

LANE showed two patients, a man and a young child, in whom he had successfully made use of the femur of a rabbit to make good the deformity caused by the absence (congenital in the child's case) of the greater part of the ulna. In each case the deformity was remedied and function was restored, the bone taking the place of the normal bone, as was shown by the radiographs. The femurs were fastened in position by fine wires.

At the Pathological Society of Manchester, November 9th, STODDART gave the result of an autopsy upon an alcoholic dement who had died from peritonitis. There was a growth extending along the mesenteric border of the stomach, small and large intestines clear to the anus. It was limited to the alimentary canal. Microscopically it was a spheroidal-celled carcinoma. The anomalous distribution of the growth could be explained in two ways: The first was that the cancer began in the stomach, the rest of the intestinal tract being infected through the food-stream, the infected particles becoming arrested at the junction of the intestinal and mesenteric lymphatics; the second was that the whole growth arose on account of a rod of sub-notochordal mesoblast with dormant hypoblastic characters, assuming those characters in advanced life and giving rise to the epithelial growth.

RAMSAY read a paper on "Pure Anesthetics" at the Society of Anesthetists, November 17th. If chloroform is given in the presence of ligated gas or lamps an unpleasant pungent odor is produced, which attacks the nose, throat and eyes. It is carbonyl-chlorid and results from combustion of chloroform vapor. At ordinary temperatures it condenses to a colorless liquid, and in the presence of moisture it decomposes into carbonic acid and hydrochloric acid. The best test for this impurity is to breath a little of the chloroform, when if carbonyl-chlorid is present, it will irritate the throat. It can be removed by shaking the chloroform with slaked lime and filtering. It has been proved by statistics that the after effects of a chemically pure chloroform are not as marked as those following the use of a less-pure article. Ether, which has been exposed to light and air sometimes has a sticky residue, probably the peroxid of ether. It can best be purified by shaking it with metallic mercury.

SOCIETY PROCEEDINGS.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Proceedings of the Eleventh Annual Meeting, Held at Memphis, Tennessee, December 6, 7, and 8, 1898.

(Continued from page 813.)

DR. LEWIS S. MCMURTRY of Louisville, Ky., read a paper on

THE TREATMENT OF CANCER OF THE UTERUS.

He said that the treatment of uterine cancer has not shared proportionately in the great advance of modern pelvic surgery. While other diseases which were long the opprobria of medical and surgical science and art have been made amenable to surgical treatment, the treatment of cancer of the uterus is practically where it was twenty years ago. Cancer of the corpus uteri is rare in comparison with cancer of the cervix, but not so uncommon as was formerly supposed. Cancer of the cervix originates (1) in the squamous epithelium of the vaginal portion of the cervix; (2) in the cylindrical epithelium of the cervical mucosa, and (3) in the epithelial lining of the cervical glands. Cancer of the body of the uterus originates in the epithelial structures of the endometrium.

The essayist referred to the statistics of vaginal hysterectomy as given by Pozzi in the third edition of his treatise on gynecology, an analysis of which does not strengthen or inspire confidence in the ultimate results of this procedure. He said that claims are being made for the permanent cure of uterine cancer by hysterectomy which cannot be realized. Of all patients having uterine cancer who apply for treatment, only a small proportion are within the scope of a clean extirpation by vaginal hysterectomy. The large number of subjects in whom the disease recurs at the site of operation within a few weeks demonstrates that the operation is in most cases simply a resection. His personal experience with this operation has been discouraging. Vaginal hysterectomy for cancer has never been a favored operation with him. During

the past year he has performed the operation in five cases which were selected as most favorable for permanent cure. In all the patients the disease was discovered early, and, so far as macroscopic evidence could show, it was limited to the uterus itself. The organ was normally mobile. Of these five patients treated by vaginal hysterectomy, two had recurrence—one in the bladder, the other in the vaginal fornix at the cicatrix—within five months from the operation. The patients were under fifty years of age and well nourished. The operation was done with a view of going far beyond the region of probable infiltration, and removing the appendages with the uterus. Based on his own previous experience, and that of other operators, it is doubtful if one of the three remaining patients will be living at the end of three years from the time of operation.

In conclusion, the speaker considered in detail the choice of operation for the several classes of cases of carcinoma of the uterus which are presented to the surgeon for treatment. For advanced cases, when the entire field of evident invasion cannot be removed, he advocated thorough curettage, scraping away necrosed tissues, emptying obstructed pus accumulations, washing out débris, and establishing drainage and antisepsis. Such local treatment will reduce septic intoxication, prolong life, and promote comfort. All operations for radical cure should be limited to cases in which the disease is recognized sufficiently early for thorough removal of invaded structures. This will be best accomplished in the majority of cases by abdominal section and removal of the uterus from above, including liberal portions of adjacent structures, especially the upper portion of the vagina, where implication from the cervix is so often found. While liberal excision of suspicious areas of tissue should be carried out it will rarely be found necessary to remove the subperitoneal lymphatic glands, since their enlargement has been often found to be inflammatory in character instead of cancerous. The field of vaginal hysterectomy should be limited to the few cases of early diagnosis in which operation can be performed before deep extension of the disease.

DR. WILLIAM L. RODMAN asked the members to give their experience relative to the frequency of cancer in the black and white races. He was rather surprised to hear of the infrequency of the disease in the negro women. According to the last census-statistics of Billings, cancer of the uterus is more common at all ages in the black than in the white race. This is also the experience of Matas, who has examined the records at the Charity Hospital at New Orleans. An examination of all deaths recorded by the Health Department of Louisville for the past thirty years corroborated the same view.

DR. ERNEST S. LEWIS of New Orleans stated that while he had not observed a very marked difference in the relative immunity of negro women to cancer of the uterus, still if his experience is not at fault, he thinks, owing to their uncleanliness, their mode of living, and to the more frequent accidents to which they are subject during labor, they are particularly prone to cancer of the uterus. With regard to the results of all operations for cancer of the uterus, he endorsed everything Dr. McMurtry had said.

DR. VIRGIL O. HARDON of Atlanta said that during his seven-years' connection with the Grady Hospital he had reason to believe that cancer of the uterus was more frequent in negro women than in white women.

DR. HOWARD A. KELLY of Baltimore remarked that he was astounded at the trend the discussion had taken because he had seen dozens of patients with cancer of the uterus who had remained well for a number of years after having undergone removal of the uterus either by the vagina or by the abdomen. He finds carcinoma of the uterus as frequently in negroes as in white women.

DR. J. WESLEY BOVEE of Washington, D. C., said that his experience in the radical treatment of cancer of the uterus has been more satisfactory than that of Dr. McMurtry. He knows of a good many patients upon whom he has operated who have gone on for three years or more without a recurrence of the disease. He has performed three operations, after the manner described by Werder in the *American Journal of Obstetrics* of last winter, and is much pleased. In each case he adopted the abdominal rather than the vaginal route, believing a more radical operation could be performed by this method. He has great hopes for the future treatment of cancer of the uterus by complete abdominal hysterectomy, undertaken early.

He then read a paper, entitled

THE USE AND ABUSE OF NORMAL SALT SOLUTION.

The term normal salt solution has been used interchangeably with artificial serum. Various compositions and strengths of the constituent elements of the blood have been used under the name of normal salt solution. According to Kirke's "Hand-Book of Physiology," salt exists in the blood plasma in the proportion of 5.546 parts per 1000, and 6 per cent. is a good practical formula. Other ingredients, *i.e.*, egg-albumen, have been added to the salt which really makes an artificial serum instead of normal salt solution.

Of the five different routes through which it is introduced, the intra-arterial, suggested by Dawbarn, is considered unsafe in all conditions and should *not* be practised. The subcutaneous is the most useful for general use. In emergency work the intravenous method will often be needed in severe hemorrhage and rectal enemata of the solution will be found of great advantage in nearly all cases in which no bowel lesion is to be combatted. In abdominal surgery the peritoneal cavity will be selected for its introduction, and even in vaginal opening of the peritoneal cavity, as in hysterectomy, he has thrown considerable quantities into the peritoneal cavity, the hips being elevated at the time and the peritoneal opening closed directly afterward. The intravenous route, usually the most rapid, may be rendered slower than the subcutaneous by difficulty of finding a vein and successfully introducing the cannula.

The physiologic action of normal salt solution is that of powerful stimulant to the cardiac ganglia and the nerve-centers. The skin, kidney, and intestinal functions are

stimulated markedly and other organs are likewise affected. Osmosis is markedly promoted by it and as a result of increased arterial tension the blood supply to the heart muscle is much increased. It has a hemostatic effect when supplied locally to raw surfaces, lessening oozing by stimulating and contracting the smaller vessels. According to Hayem and others it augments the number of red blood-corpuscles. It is eliminated by the skin, changing the chemical reaction of the perspiration and heavily loading it with salt. The kidneys also carry away an enormous amount of it when large quantities of it have been introduced into the tissues. The lungs remove it freely, it having been noticed in crystals on the lips after its free use. Autopsies after its use under the skin have shown a considerable quantity of it in the intestines, demonstrating that it is thrown off by this route.

In surgery the principal indications for its use are shock, hemorrhage, and sepsis. In shock it should be employed early, on the table during operations, or even before the operation has been undertaken in bad cases, or after operation in milder ones. Severe hemorrhage is to be treated in the same manner, though only after the flow of blood has been checked. If the hemorrhage be severe, the intravenous route may be employed, it being about the only indication for this method. In the author's abdominal work he almost invariably leaves a considerable quantity of salt solution in the peritoneal cavity. Its salutary effect is produced by its action on the abdominal viscera with which it comes in close contact. To prevent adhesions in the pelvis one or two liters suffices. It hastens absorption of stray or concealed blood-clots, septic foci, or escaped fluids by carrying them well up into the abdominal cavity in cases of pelvic surgery. In hemorrhage it is probably best to infuse small quantities and often rather than in one large amount.

Judging from the reports of experimenters the use of normal salt solution is not a harmless procedure. It is contraindicated in such conditions of the blood as hemophilia, dyscrasias, deficient fibrin, etc. It would seem not unreasonable that such a strong stimulant, coupled with its dilatation of the blood-vessels, when used in large quantities, and especially when thrown directly into them, would be very harmful in such conditions of the circulatory apparatus as myocarditis, pericardial effusion, atheroma, arteriosclerosis, cardiac degeneration, bad valvular lesions, thrombosis, and recent cerebral apoplexies. Chronic diseases of the lungs, kidneys, or liver, especially if malignant, are apt to be aggravated by it. Active hemorrhage in any location is aggravated by it. The presence of toxins in the blood has been found to retard the elimination of normal salt solution, and for that reason small quantities at a time only should be employed.

It is necessary to avoid certain accidents and mistakes in using normal salt solution. One must know the solution is sterile when it enters the tissues of the body, except by the rectum, in which case it is of no moment. Avoid air bubbles entering into blood-vessels or cellular tissue. The fluid must be of a sufficiently high temperature when it reaches the body. Chills occur from a cold solution and are dangerous to very weak patients. The vessel containing the solution as well as the tube and needle conducting it must be aseptic and thoroughly pervious; the tube should have a glass window that the rapidity of the current and the presence of any foreign body may be noted. When the solution is to be introduced through the skin, either into cellular tissue or a vein, the local surface should be cleaned as much as the limited time will permit. Probably not more than a half liter should be injected into the tissue through one puncture, as localized necrosis and a septic inflammation have resulted from overdistention of the tissue spaces. Ordinarily not more than one ounce per minute should be injected into tissue or vein. Pulmonary edema, dyspnea, headache, vertigo, mental excitement, delirium, hallucinations, severe pain in the left side occur from overdistention of veins from a too large infusion.

THE CONSERVATIVE TREATMENT OF THE DISEASED OVARY

was the title of a paper by Dr. Joseph Taber Johnson of Washington, D. C.

In the early part of the present decade quite a conservative wavelet swept over the country, and considerable harm was done to pelvic and abdominal surgery in the mild and gentle name of conservatism. Incomplete conservative operations were performed, some of which had to be completed later on by radical operations. Some of the men who claimed to be the most conservative, and attracted the timid doctors and frightened patients, were actually removing more ovaries and tubes than many of their so-called radical friends.

So much has been learned by accumulating experiences, as the domain of the gynecologist has undergone so much expansion, that real conservatism is gradually gaining ground over real radicalism to such an extent that he who presents ovaries and tubes or a fibroid uterus to a modern up-to-date medical society, has to state very good reasons why he sacrificed these important organs in their entirety to escape criticism and possibly censure. Sacrificial surgery is gradually giving way to more conservative and humane methods. He believes there is a maxim in general surgery in favor of saving every inch of the human body possible, and another that it requires a higher order of skill to save a mutilated or diseased member than it does to cut it off or to cut it out. With his present experience in abdominal surgery, he is free to confess that he can now save ovaries and tubes which he formerly thought it necessary to totally remove. The increasing skill of our abdominal surgeons and their accumulating experience in actual conservative work go to show that we are approaching nearer to that true conservatism which is the offspring of increased skill and experience. In abdominal surgery it requires a higher order of skill and a greater experience to save an organ or part of an organ than it does to remove it

The president's address was delivered by Dr. Richard Douglas of Nashville, Tenn. He made a departure from the usual or stereotyped addresses, and selected for his subject

ACUTE GENERAL PERITONITIS.

Before considering his subject proper, he spoke of the growth of the Association and the excellence of its scientific work, saying that the Association owes its existence and high standing to the indefatigable efforts of DR. W. E. B. DAVIS, the permanent secretary.

A bacteriologic classification of peritonitis is beset with many difficulties, and while the speaker was free to admit that for all practical purposes peritonitis is of bacterial origin, yet there occurs a respectable percentage of cases in which the most rigid examination fails to disclose the presence of micro-organisms. Hartmann and Moreau reported in detail such a case recently. Of 110 cases bacteriologically classified by Flexner there were 12 cases which he was obliged to consign to the idiopathic group. It is true that in all of these patients there existed conditions predisposing to peritonitis, such as cardiac, renal, or hepatic disease. In the intensely septic mycotic form of peritonitis the absence of bacteria may be accounted for by the fulminant type of the disease, death occurring from intoxication before the colonies are well established. Any effort to individualize the effect of a specific bacterium, to connect its presence with a definite pathologic phenomenon and characteristic symptomatology is as yet futile. Mikulicz avers that all forms of peritonitis run the same clinical course regardless of the bacteria that cause it. There is a law laid down by Maloz to the effect that if the peritonitis is of intestinal origin, the colon bacillus will show it; if it is of uterine origin, that is, connected with abortions or labor, the streptococcus is found. It is asserted that the colon bacillus constitutes nine-tenths of the bacteria of the digestive tract, the colon is its natural habitat, but its behavior upon gaining entrance to the peritoneal cavity depends upon many circumstances, and this bacillus has many morphologic conditions, many forms and stages. The constancy of its presence in peritonitis, since the demonstrations of Welch and others of its capacity of transmigration through the bowel, has led many to attach to it great significance as an etiologic factor, but its association with other forms of micro-organisms renders the first proposition of Maloz null and void. If we interpret Maloz's law correctly, the absence of streptococci would eliminate the possibility of peritonitis being of puerperal origin. In rebuttal of this idea, Dr. Douglas quoted from Winckel, who says: "Kroenig examined all parts of the uterus of a woman dead from infection, and found not only the superficial thrombi at the placental site thickly filled with bacteria, but also the serous lining of the peritoneum." This case shows that a woman may have a peritonitis following abortion without streptococci, and it further shows that the colon bacillus without an intestinal lesion may produce a fatal peritonitis. No doubt too much importance has been ascribed to the colon bacillus, and it is interesting to note that Tavel, who was among the first to emphasize the pathogenic powers of the bacillus coli communis, thinks now the bacillus of minor importance in the etiology of peritonitis. He holds, further, that the very name of the bacillus coli should be considered merely a collective name of many varieties of bacteria.

The conclusions that may be drawn from an etiologic study of peritonitis may be thus summarized: Traumatic peritonitis, especially the post-operative variety, is essentially a grave condition, not only because there is immediate or primary inoculation of the peritoneum, but because the conditions are all favorable for germ-culture and dissemination. Peritonitis by continuity may become general and prove rapidly fatal, but this is not the rule except in puerperal cases. Contrary to the expressed opinion of more than one writer, there is nothing peculiar about the peritoneum, of the cecum, or appendix, or the true pelvis, which accounts for the more frequent localization of inflammation in these regions than in other areas of the abdomen. The method of invasion, the activity of the process and resistance of the patient alone determine the local or general type of peritonitis. Visceral perforation, whether traumatic or pathologic, is an ideal condition for germ culture and the elaboration of toxins. Their rapid absorption and general diffusion throughout the peritoneum sufficiently explain the grave state into which the patient is precipitated. It may be asserted that the clinical course and pathologic expression depend largely upon the nature of the exciting cause, the character of the preexisting disease or injury, and the mode of invasion.

WHEN SHOULD WE OPERATE FOR APPENDICITIS?

DR. A. M. CARTLEDGE of Louisville read a paper on this subject. He drew the following conclusions: (1) Probably ninety-eight per cent. of the patients who die of acute appendicitis without operation have the fulminating variety of the disease. Operation to be of service must be performed during the first twenty-four hours, better the first twelve. (2) In view of the fact that we have no means of knowing the probable course of a given attack of appendicitis, operation, when possible, should be performed within the first twenty-four hours after the onset of symptoms. (3) Patients seen after the third day should not be operated upon until over the attack, or until purulent formations, if such take place, have been walled off, and the patient practically rid of general sepsis. An exception to this rule is the rupture of an appendiceal abscess into the peritoneal cavity, a very rare accident, when abdominal section should immediately be performed. (4) Probably as many patients recover from general septic peritonitis by the use of stimulants and purgatives as do by operations. In either event, if it is a case of true general septic peritonitis, the mortality will not be far from ninety-five per cent. If the patient is operated upon at all, no attempt at general cleaning of the cavity should be practised. The surgeon should quickly assist Nature to take care of the patient by removing the foci. To do more is to add the shock of an unbearable operation to an already nearly exhausted vitality. (5) Subject to interval operation, patients who have suffered unmistakable attacks of the disease. (6) Do not operate too soon after a severe attack with many adhesions; the operation will be greatly simplified by waiting a few weeks longer. In the meantime, keep the patient upon light diet and little exercise. Patients do

not usually have a recurrence until the adhesions or splints have been removed by absorption. The mortality from interval operations should not be more than one per cent.

DR. GEORGE H. NOBLE of Atlanta, read a paper on

URETERAL ANASTOMOSIS.

He gave an analysis of thirty cases collected from literature, and divided them into two classes: First, ureteral anastomosis, or union of the ureter end to end or end to side; second, ureteral implantation into the bladder. On July 2, 1898, the essayist ligated the ureter with the ovarian vessels and Fallopian tubes in a case of large extraperitoneal fibroma. This was the very first ligature applied in doing hysterectomy. The bladder end was split about three-eighths of an inch, and as much of the mucous membrane as could be drawn out was cut away; then the upper or kidney end of the ureter was invaginated into it, a mattress suture being used for the purpose. The split was then closed with fine sutures, making a snugly fitting cuff around the opposing end with no mucosa intervening. Small silk was used to stitch the raw edge of the inferior segment around and to the sides of the upper section. A peritoneal cuff was thrown around the joint thus made and the ureter buried behind the peritoneum. The entire work was conducted with the aid of a ureteral catheter, which had been introduced through the ureter into the bladder and drawn out of the urethra with a pair of forceps. The upper end was passed into the kidney end of the ureter. This served a useful purpose, the entire manipulation being greatly facilitated and preventing obstruction of the ureter by crowding down the cut end of the mucosa just below the line of union. This patient had suffered from absorption of pus for a number of weeks from double pyosalpinx, was emaciated and thoroughly septic. Her temperature just before going upon the operating-table was 103° F., and had been running equally as high during the time she had been in the hospital and perhaps longer. Her pulse was 130 per minute, weak and thready. Thus this anastomosis was done under unfavorable conditions, but successfully.

In October, 1898, he did a successful resection of the left ureter in a case of extraperitoneal extension of sarcoma of the ovary. About one and one-half inches of the duct was removed and the ends united as above. The peritoneum was stripped from the entire left half of the pelvis. The bladder was separated from the upper portion of the vagina, and also from the horizontal ramus of the pubic bone, and drawn up to the left side to the ileopectineal line to cover or bury the ureter, and fastened with a silken suture. In this instance the ureteral catheter was introduced on a stilette and being stiffened by it passed directly out of the urethra from the ureter; thus the use of forceps was unnecessary to fish it out of the bladder. Abdominal and vaginal gauze-drains were used. There was no leakage.

There are several features necessary to success in performing ureteral anastomosis aside from thorough asepsis: (1) Perfect coaptation or invagination. This must be done in such a way that no mucous membrane can slip between the two ends of the ureter. (2) The ureteral artery should be preserved in its continuity to the ends of the ureter. If this vessel be destroyed when the ureter has been dissected loose from its attachments, it will perish beyond the point where it ceases to receive its blood supply. The ends of the ureter should be cut back to the point where the artery is intact lest under diminished blood supply and tension it should perish. (3) All strain or tension must be relieved. Should union occur by first intention, the parts will separate as soon as the sutures cut out or are released. (4) There must be no obstruction to the flow of urine.

CARCINOMA OF THE BREAST.

DR. WILLIS F. WESTMORELAND of Atlanta read a paper on this subject, in which he said that carcinoma now presents even a more serious problem than formerly on account of its rapid increase. The proportionate mortality from cancer is four and a half times greater now than half a century ago. No other disease can show anything like such an immense increase. According to statistics, two out of every five cases of carcinoma in the female are of the breast. More than three-fourths of all the tumors occurring in the breast are carcinoma, or, to be exact, of 637 tumors more than 503, or 83.20 per cent., were carcinoma, leaving only 107, or 16.79 per cent. to represent all other forms of neoplasms. The essayist follows the Halsted method in operating for carcinoma of the breast. He believes, however, Dr. Joseph Bloodgood was the first to demonstrate the advantages of completely cleaning out the postero-internal subscapular region by the supraclavicular route. The results of the Halsted operation, in the opinion of the essayist, depend upon the ability of the individual operator, the earliness in seeing the case, and his closeness in following Halsted's technic.

DR. I. S. STONE of Washington, D. C., contributed a paper on

THE RARITY OF OVARIAN CYSTS IN NEGRESSES.

After several years' experience in a hospital for women, where a large number of negresses are annually treated for gynecologic diseases, and where cases of uterine myomata are frequent, the writer has noticed the extreme rarity of ovarian neoplasms, and especially of the multilocular variety in this race. He addressed letters to all the members of the Association and to several other prominent surgeons elsewhere, and of the large number who replied to his inquiry there was almost universal acquiescence in the position taken from him, save by one important medical center, the city of New Orleans. According to the records from the hospitals of that city, cysts of the ovary of all classes are rather more frequent in the negro than in the white. Leaving aside this one source, the author advanced overwhelming testimony favoring the view that ovarian tumors are exceedingly rare in the negro race. He made a careful distinction between multilocular and unilocular cysts, because there can be no doubt about a diagnosis at the time of operation when a multilocular cyst is found. It is otherwise

with parovarian cysts, or those of the broad ligament, etc., which are perhaps classified as ovarian, and their removal called ovariotomy in hospital reports, or operation-lists, when, strictly speaking, they are not ovarian tumors. He has frequently operated for dermoid, papillomatous, parovian, and broad-ligament cysts in negresses (although most of these in mixed cases), but has not seen a multilocular ovarian cyst.

DR. F. W. PARHAM of New Orleans read a paper on

RESECTION OF THE THORACIC WALL FOR TUMORS GROWING FROM THE THORACIC SKELETON.

He reported two such operations of his own with successful results. Both operations widely opened the pleural cavity and the lung collapsed in both. In the first the collapse was relieved only when the great pectoral muscle was brought down and sutured to the rent in the pleura. In the other signal service was rendered by the Fell–O'Dwyer apparatus for maintaining regular respiration. He believes the perfection of this apparatus and its application in skilful hands will greatly aid in the developing of the surgery of the chest. He had collected reports of all cases operated on up to date with a mortality of twenty-five per cent. for the intrapleural operations for tumors of the chest wall.

DR. W. L. ROBINSON of Danville, Va., presented a

CLINICAL REPORT OF THE USE OF ANTISTREPTOCOCCIC SERUM IN SEVEN CASES OF PUERPERAL SEPTICEMIA, FOUR OF POST-OPERATIVE SEPSIS, THREE OF SEPTIC CELLULITIS, AND TWO OF ERYSIPELAS.

The use of antistreptococcic serum in puerperal fever comprises seven cases treated by him, the patients having high fever, rapid, weak pulse, characteristic breath, chilliness, nausea, insomnia, and pelvic tenderness, with scanty, fetid lochia. From 12 to 20 c.c. of the serum was injected after the usual treatment had failed, including irrigations, intra-uterine and vaginal, sealing abrasions of the cervix and perineum, saline injections, purgatives, stimulants, etc., with prompt improvement in the general condition, rapid fall of temperature, lowering of pulse-rate, and complete recovery. The effect was manifest in from eight to sixteen hours in the majority of cases. In the three post-operative cases of sepsis, seemingly hopeless, all the usual treatment failing, the serum in twelve hours transformed every symptom of high fever, chilliness, rapid, weak pulse, diarrhea, etc., into a hopeful condition, resulting in rapid recovery. Pain subsided in twelve hours, fever in eight hours, diarrhea in forty-eight hours. One case was a vaginal hysterectomy; the second patient was operated on for the removal of pus-tubes, and the third had a vaginal hysterectomy. Two cases of septic cellulitis consisted of suppurative cellulitis of the hand, commencing in a finger, one from injury from a rusty nail, and the other from the spur of a cock. Both had been treated by general alterative tonics and locally by improved antiseptic measures, but the disease progressed daily, involving new tissue till the serum was used, which promptly arrested the progress of the disease in both cases and saved the hands. A third case was a gunshot wound of the ankle, with marked septic prostration, chills, diarrhea, etc., which was dissipated promptly by the use of the serum so far as fever and general septic symptoms were concerned. There were two cases of erysipelas, one in a patient sixteen years of age, due to an abscess following extraction of a tooth, discharging at two points on the neck. Redness and swelling covered one-half of the face, nose, and head. Temperature 104.4° F., pulse 140, delirium, vomiting, chilliness, etc. Ten c. c. of the serum was injected at 9 P.M., resulting in fall of temperature to 100° F. Next morning there was complete arrest of all symptoms, followed by prompt recovery. The second case was one of nephritis. The patient had puffed eyelids and face. Erysipelas of the thigh developed, which became hard, red, and shiny. There was marked delirium. Two injections during twenty-four hours rendered the patient convalescent in thirty-six hours. The serum used was that of Parke, Davis & Co.

DR. J. B. MURFREE of Murfreesboro, Tenn., followed with a paper on

PENETRATING WOUNDS OF THE CHEST.

Penetrating wounds of the chest vary in their extent, character, and severity. They vary from a small perforation with a delicate knife-blade or small bullet, merely separating the tissues without inflicting any serious injury to a fearful laceration with great loss of tissue or serious damage to an organ produced by a large knife or a Minie ball. Wounds penetrating the chest are dangerous from hemorrhage, from the admission of air into the pleural cavity, producing collapse of the lungs, from emphysema, from empyema, from septicemia, and from exhaustion. When a large vessel is injured death quickly ensues from loss of blood; while injury to smaller vessels may endanger life and even prove fatal from continued or frequently repeated hemorrhage.

DR. GEORGE S. Brown of Birmingham, Ala., reported a case of vesicorectal fistula of eight-years' standing, the result of perineal lithotomy, with cure after ten operations.

The following officers were elected for the ensuing year:

President, Dr. Joseph Taber Johnson, Washington, D. C.; vice-presidents, Drs. F. W. Parham, New Orleans, and W. L. Robinson, Danville, Va.; secretary, Dr. W. E. B. Davis, Birmingham, Ala.; treasurer, Dr. A. M. Cartledge, Louisville, Ky. To fill vacancy in the Council—Dr. L. McLane Tiffany, Baltimore, Md. Place of meeting, New Orleans; time, to be determined by the secretary with advice of the Council. After the presentation and adoption of resolutions of thanks, the Association adjourned.

REVIEWS.

A TREATISE ON APHASIA AND OTHER SPEECH DEFECTS. By H. CHARLTON BASTIAN, M.A., M.D., F.R.S. New York: D. Appleton & Company, 1898.

THE literature on aphasia is enormous. Perhaps no other symptom in neurology has received the attention, and has been the object of so much discussion as those

anomalies and perversions of the receptive and expressive functions of the brain involved in language. Dr. Bastian has attempted in the seventeen chapters which comprise this book to present the best established facts relating to these perverted functions of speech.

The book, after a general physiologic and psychologic introduction, takes up the consideration of the existing relations between thought and language. The following chapter is devoted to classification, after which the defects of speech and writing due to structural or functional degradation of motor-centers are considered. The effects of structural and functional disabilities of the various centers concerned in language are then reviewed. This part of the book was outlined in the author's Lumleian Lectures before the College of Physicians of London in 1897. Paraphasia and paragraphia are considered in a chapter, as are the defects due to lesions of the commissures between the different cortical centers involved in the mechanism of language. A very interesting chapter is given to the consideration of the capacity for exercising civil rights. An adequate consideration of the etiology, diagnosis, and prognosis of speech-defects follows, and the work concludes with the discussion of the treatment of these perverted conditions.

To say the least, when one deals with these disturbances he is bound to fall into theory or speculation, or both. There are few works which deal with aphasia which are deprived of these defects, for such they must be called when they appear in a purely scientific treatise. If writers would pay more attention to the clinical and pathologic data than to the purely metaphysical, much of the obscurity with which these "speech" defects are veiled would be removed. Dr. Bastian has brought forward cases where he could to assist in establishing facts which should serve as a basis for speculation. It is needless to say that anything coming from Dr. Bastian's pen is deserving of study and attention, and this work, perhaps, as much so as any of his other contributions to neurologic science.

LABORATORY WORK IN PHYSIOLOGICAL CHEMISTRY. By FREDERICK G. NOVY, Sc.D., M.D. Second edition, revised and enlarged. Ann Arbor: George Wahr, 1898.

THIS work, as its name implies, is a laboratory manual, and although its first edition appeared only a few years ago, nevertheless this second edition is most welcome on account of the enormous advances which the subject of which it treats has made during the interval.

The chapter of principal interest, that on Proteins, contains a classification which differs somewhat from the recent one of Neumeister and that of Chittenden, but the one before us is well subdivided, and its three major divisions are most clearly differentiated. Not sufficient emphasis can be employed to indicate the value of quantitative estimations in the clinical examinations of physiologic secretions, and the chapter which treats of this subject might be of use to many in the active practice of medicine. Gross clinical methods, as they are at present understood by the physician, show us but little of what actually is present in these materials, and it is only by the most carefully performed quantitative analyses that we are enabled to judge the change in the condition of the patient under treatment. The examination of gastric juice, blood, milk, urine, pancreatic secretion, bile, and saliva is fully explained, and the quantitative determinations of the constituents of the first four are given in detail.

A table for the examination of urine, list of reagents and a short index completes the work, which might be recommended to any one working in this special department of chemistry.

ATLAS OF METHODS OF CHEMICAL INVESTIGATION. By Dr. CHRISTFRIED JAKOB, formerly First Assistant in the Medical Clinic at Erlangen. Authorized translation from the German. Edited by AUGUSTUS ESHNER, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic. Philadelphia: W. B. Saunders, 1898.

THIS work has no merits over its numerous predecessors of like character, save the abundance of well executed illustrations whence it derives its title. A very conventional word picture of the diseases accompanies the illustrations, of which there are 68 full-sized plates. The latter half of the work is devoted to methods of clinical examination. Differential diagnosis, so intensely significant to the medical neophyte in grasping the essential differences in diseases, is much neglected. In attempting still further to condense into this hand-atlas the subjects, urinanalysis, blood examinations, gastric analysis, and clinical bacteriology, the author has erred. The epitomized style adds both to the difficulty of reading and of memorizing.

THERAPEUTIC HINTS.

For Cardiac Weakness after Scarlatina.—

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LXXIII. NEW YORK, SATURDAY, DECEMBER 31, 1898. No. 27.

ORIGINAL ARTICLES.

GOUTY AND RHEUMATIC AFFECTIONS OF THE EAR.

BY SEYMOUR OPPENHEIMER, M.D.,

OF NEW YORK;

ATTENDING LARYNGOLOGIST TO BELLEVUE HOSPITAL, OUT-PATIENT DEPARTMENT; ATTENDING LARYNGOLOGIST TO THE UNIVERSITY MEDICAL COLLEGE DISPENSARY.

THE more or less intimate relationship existing between gout and rheumatism, in this country at least, and the conflicting theories suggestive of the etiology of the two diseases, precludes a separate consideration of each when studied as to the effects produced on the auditory apparatus. For the purpose of describing the local effects of these diseases as especially concerning the otologist, we may in general consider the two as one affection, except in a few instances, which will be discussed in their appropriate place.

We must consider rheumatism as partaking of two forms, the acute and the chronic, the ear being occasionally involved in both varieties. In the acute form the joints are the parts mainly affected; there is hyperemia and swelling of the synovial membrane and the ligamentous tissue, the fluid lubricating the joint becomes turbid, albumin, and fibrin being present in increased amount. In chronic rheumatic affections involving the joints the synovial fluid is diminished in amount, the cartilages are thickened, as is also the capsule surrounding the articular surfaces, the sheaths of the tendons in the immediate vicinity of the involved joint undergo similar alterations, and the movements not only of the joints, but also of the neighboring muscles, are restricted. In addition to this, in the form under consideration, the nerves supplying the parts undergo pathological change, and consequently, from the peripheral neuritis resulting, nutrition and innervation suffer, and atrophy of the affected parts, and especially of the muscles, supervenes. The blood-vessels also become the seat of a slowly developing sclerosis, adding to the changes already observed.

In the study of the morbid anatomy of gout an excess of uric acid is found in the parts directly involved by the disease. This extraneous substance, acting as an irritant, produces a local coagulation necrosis, with inflammation, hyperemia, swelling of the ligamentous tissues, and effusion into the joint.

A study of the histologic structures of the auricle and external auditory canal reveals the presence of a large amount of fibrous tissue and cartilage, the two tissues especially susceptible to the morbific influences of the affections under consideration. The middle ear consists essentially of a cavity with two openings, the Eustachian tube anteriorly and the antrum and attic posteriorly. Enclosed in this central cavity are the ossicles with their minute and complicated system of articulations, the stapes with the fenestrum ovale, the incus with the stapes and malleus, and the malleus with the incus, membrana tympani, and wall of the tympanic cavity. The mucous membrane of the middle ear being closely adherent to the bony walls in part replaces the periosteum, and with its numerous folds divides the cavity into a number of secondary spaces. Concerning the inner ear, the blood-vessels only need be considered, the injurious effects of gout and rheumatism upon this portion of the auditory apparatus depending upon changes in the vessels, and rarely affecting the delicate nerve-filaments of the parts.

Although gouty and rheumatic affections of the auricle were studied many years ago, it was not until 1849 that W. Harvey, in a systematic paper, directed special attention to the morbid changes noted in the auditory apparatus resulting from these affections. He called attention to the fact that both gout and rheumatism affect the ear without any other changes in this organ being present, and also observed that the ear, already the seat of other pathological alterations, is liable to be affected in gouty subjects, thus in a way changing the character of the disease previously existing.

Accurate statistics as to the frequency with which the ear is affected are not easily obtained, the general opinion, however, being that the internal ear and auditory nerve are very rarely affected, the tympanic cavity and membrana tympani more often than is generally supposed, while the external auditory canal and auricle are quite commonly influenced by the general affections. Especially will this relationship be evident if a careful history be obtained in all ear diseases coming under observation. Dench[1] says that gout and rheumatism exert more influence on the ear than is commonly supposed, and that it is not necessary that there be constitutional evidences of the two affections, but the ear may be affected through a hereditary diathesis. The susceptibility of the ear in certain individuals to the

injurious effects of gout and rheumatism is explainable by the large amount of fibrous tissue composing portions of the auditory apparatus, the selective powers of these diseases, as has been seen, being well marked for this form of tissue, entering as it does into the composition of the larger part of the auricle and external canal, and forming to a great extent the important ossicular articulations. Richey,[3] in a paper on this subject, considered that the minute joints of the ossicles are liable to attacks of rheumatic arthritis from their exposure to atmospheric changes. That the rheumatic diathesis manifests itself in acute exacerbations as the result of sudden or prolonged alterations in the humidity of the atmosphere is well known, and no reasons exist when the disease is apparently limited to the joints of the ossicles why it should not show itself here, as it does in other articular surfaces of the body.

From the otologist's point of view we are concerned with gout and rheumatism as being either hereditary or acquired. The acquired form of the disease, as seen in the usual way and due to causes originating in the affected individual, manifests itself in the aural apparatus in various ways, being either clearly defined and then readily recognized, or may simply show itself as alterating the character of some diseased process already present in the ear. The obstinate character of many ear troubles, especially eczema of the external auditory canal, and serous middle-ear catarrh is due in a considerable proportion of cases to the gouty or rheumatic diathesis. Hereditary gout, as observed in this location, may appear a short time after birth or later in life, the first rarely, but during adult life much more commonly. D'Aguanno[3] reported three cases of tardy hereditary gout of the ear in which deafness developed as soon as the patients arrived at the age of puberty. No other causes for the affection were found, and the nose and nasopharynx presented no deviation from the normal. The father had been affected with the gouty diathesis for years, and as the result of D'Aguanno's study of these and similar cases, he concluded that among the ordinary forms of hereditary gout of the ear there is a late variety which usually manifests itself at the age of from fifteen to twenty years.

Aural involvement from both affections occurs most often in advanced life and in males; this is especially so as regards the serous form of otitis, while the chronic sclerotic variety of middle-ear disease dependent upon rheumatic diathesis is not seen at any definite age, but occurs most frequently in the female sex, and is associated with muscular rheumatism. Acute myringitis depending upon the acute form of rheumatism and gout occurs at any time, age and sex apparently bearing no relation to this complication. Destructive processes of the middle and internal ear occur most frequently in males and at an advanced period of life, the patient suffering from the rheumatic or gouty diathesis a number of years before the ear becomes involved. General evidences of rheumatism may not be present, the auditory apparatus being affected primarily, and on the subsidence of the aural inflammation the nature of the disease will be seen by the occurrence of rheumatism of one or more large joints of the body. In gouty patients well-marked evidences of the disease elsewhere are usually found before the ear becomes affected, although the hereditary form may not show itself anywhere but in the ear for a considerable period. In the large proportion of patients suffering from well marked gout liability to occasional subacute dermatoses of the meatus is observed.

Both gouty and rheumatic affections objectively and subjectively differ considerably when various parts of the auditory apparatus are affected. The auricle is very commonly the seat of deposits of nodular urates in gouty subjects; these crystals or amorphous masses are generally situated underneath the skin of the helix, and do little harm; occasionally from pressure inflammation is produced, the cause being recognized by the presence of a foreign body underneath the cutaneous surface. In both gout and rheumatism of long standing the external auditory canal is frequently affected with a localized, subacute form of eczema, mild in character, but very resistant to treatment, and leading to changes in the cutaneous lining. In many cases of eczema in this locality treatment as usually applied is of no avail, and the patient improves only after constitutional measures directed to the primary disease have been instituted. The eczematous patch presents nothing of a diagnostic nature, a history of the case as regards the presence of gout or rheumatism, and the results of treatment alone allowing a proper diagnosis to be made. Resulting from denudation of the cutaneous lining of the canal and the increased moisture present there is a considerable tendency to the development of vegetable parasites on the eczematous area.

Toynbee[4] referred osteomata of the canal to the gouty-rheumatic diathesis, and although exostoses occur in this locality quite frequently in individuals of this class, yet no direct causal relation has been fully established. From the deposit of urates under the skin of the meatus a furuncle forms, while in severe attacks of rheumatism a general condition of furunculosis of both external auditory canals is occasionally seen. The membrana tympani is rarely affected without the middle ear at the same time be-

ing involved, but occasionally during an acute, violent attack of gout transitory pain of the ear will be complained of, lasting for a few hours and rapidly passing away. If the membrana tympani be examined, intense congestion of the manubrial plexus will be seen, the middle ear apparently not being involved, but when it is affected the membrana tympani also participates in the morbid process. Both rheumatism and gout, but especially the former, produce their marked effects on the tissues of the tympanic cavity; these changes are varied, but in general may be divided into two main divisions; first, an acute and destructive process, and, second, a chronic and insidious affection.

Acute rheumatoid otitis occurs during an attack of acute rheumatism; intense pain is complained of in the affected ear, paroxysmal in nature and affecting the entire side of the head, tinnitus, slight at first, increasing in intensity until the patient is almost distracted with the sounds in his head, and when the pain subsides there is a feeling of numbness of the affected ear and of the same side of the head. On examination of the middle ear under good illumination the drum-membrane will be seen to be intensely red and differing from the color usually observed in acute myringitis, being of the shade known as flamingo. If the treatment is successful the affection rapidly subsides, and the ear may speedily become normal, or a moderate amount of deafness may last for a few weeks. Uncontrolled, the affection increases in intensity, pus is developed, and necrosis of the bone may result, the mastoid possibly becoming involved. This violent, acute form of rheumatic inflammation may lead to entire destruction of the ossicles and adjacent bone. Again, the acute form may vary in a most striking manner in different individuals, being in no way affected by the intensity of the disease elsewhere, although should a number of joints be inflamed at the same time the tendency to ear involvement is decidedly increased. In other cases it may manifest itself by redness of the drum-head, moderate degree of deafness, and a feeling of stuffiness in the ears, pain and tinnitus being entirely absent. This condition remains for a few days, the usual treatment being of no avail, and then disappears without apparent cause, only to return when another rheumatic attack is imminent. A third form is characterized by intense pain only, the middle ear on inspection apparently being normal, while the tympanic membrane will give no evidence of the presence of disease of the parts; impairment of hearing, and, in fact, all the symptoms of acute otitis, except the pain, are absent. This may last for an indefinite time, and relief will not be obtained until the rheumatic condition is ascertained and proper general antirheumatic remedies employed, for local treatment seems useless. As a result of these acute processes in the middle ear, marked alterations in the functions of the parts will result, but they differ in no way from those observed after non-rheumatic inflammations, and need not concern us here.

Slowly progressing changes in the tympanic cavity occur both from gout and rheumatism, and are independent of the acute affections just described. These changes usually develop early in an acute exacerbation of long-standing rheumatism, the fibrous tissue being primarily involved and, finally, the nervous tissues participate in the pathological process. There are usually two distinct chronic affections involving the middle ear in which the gouty-rheumatic diathesis exerts a great amount of influence as a causative factor. The most common of these is chronic sclerosis of the drum-cavity, the fibrous tissues being especially involved. Previous to the sclerotic changes becoming characteristic, there is an initial semiacute form of inflammation present. This occurs during an attack of the general disease and continues in the interval. The membrana tympani is neither normal nor red in color, while other symptoms are absent until the ossicular articulations become ankylosed and marked fibroid changes render the functions of the parts less and less acute until deafness becomes almost, if not quite, complete. This form of middle-ear sclerosis differs only in its etiology from that due to other causes, but it should be remembered that, as a result of gout and rheumatism, the latter especially, the brunt of the disease is borne by the joints of the ossicles, and therefore serious damage to the hearing will eventually result.

The other form of otitis in which these general affections exert a distinct influence is that characterized by a watery, serous discharge from the middle ear. Pus is never present, and the affection is not always confined to the middle, but frequently invades the external ear. Sexton[5] says that the serous form of otitis media is found nearly always in rheumatic or gouty subjects. The progress of the disease is slow, months and years passing before cure is complete, and relapses are frequent, depending upon the presence or absence of the constitutional disorder.

The delicate structures of the labyrinth and cochlea apparently do not participate in the morbid process, except when the middle ear and adjoining parts undergo extensive necrosis the result of a severe attack of rheumatism. As an indirect internal ear involvement, however, changes in the vestibule and cochlea are occasionally found resulting from arteriosclerosis of the minute vessels ramifying

through these regions. As the result of long-continued rheumatism in advanced life there is a considerable degree of degeneration of the arterial walls throughout more or less of the entire arterial system, the peripheral vessels supplying special organs, such as the one under consideration, from their small caliber and delicacy, being less resistant to these degenerative processes. In the internal ear these changes are occasionally manifested, the structures composing the arterial walls becoming degenerated and rigid from deposits of lime salts. From the diminished resistance of the diseased vessels to an increased blood-pressure rupture occurs, and the ordinary symptom-complex of labyrinthin hemorrhage is produced. The patient complains of irregular subjective forms of tinnitus with impairment of hearing and vertigo, varying with the amount of destruction in the internal ear. When the vessel-wall ruptures these symptoms appear very rapidly, but may rarely develop in an insidious manner, several months elapsing before becoming well defined, and in this case the blood is not poured out through a rupture of the arterial wall, but escapes by capillary oozing.

Rheumatic paralysis of the auditory nerve has been described by McBride[6] as occurring during the course of acute rheumatism; deafness is marked and bone conduction is diminished or lost, but vertigo does not always occur. The affection is but temporary, and as the general disorder subsides the aural symptoms gradually disappear, a slight impairment of hearing alone remaining.

The diagnosis of these changes in the auditory apparatus is readily made if attention be directed to the etiologic influences of the gouty-rheumatic diathesis in all stubborn cases of the various forms of ear affections. The prognosis will, of course, depend upon the original cause of the ear affection, in general being good in both gout and rheumatism, and depending upon the promptness with which general treatment is instituted. Local treatment, except in acute inflammations, is of little value, general antirheumatic medication alone being of service.

A New Chemical Substance.—Dr. Becquerel of Paris, on behalf of the discoverers, Curie and Bremona, has announced to the Academy of Sciences, the discovery of a new chemical substance akin to barium. It is sensitive to light and has been named radium.

THE TREATMENT OF HYSTERIA.

By DARWIN R. STOCKLEY, M.D.,
of Evanston, Ill.

The term "hysteria" is applied to an unusually varied group of manifestations of functional disturbances of the nervous system. Defective hereditary endowment, unequal and inharmonious development, improper training, and unfavorable environment are among the predisposing factors. Exhibitions of lack of will power, of excessive emotional disturbance, of extreme susceptibility to external impressions, of great fondness for sympathy, and of a surprising simulation of other diseases are among the characteristic symptoms. The potentiality of hysteric symptoms is possessed by every one, and under favoring circumstances will be manifested. It is only in degenerates that hysteria becomes a disease. The frequent close resemblance to other diseases, and the common association of symptoms with those which have an organic basis render the recognition of hysteria a problem of great difficulty.

While the prognosis of hysteric manifestations is not unfavorable, the successful treatment of the disease requires more tact, skill, and patience than any other disease of the nervous system. The physician may first see the patient in a hysteric convulsion accompanied by one or more of the "stigmata." His first duty is to protect the patient from violence. Mechanical measures are usually employed, the mind of the patient controlled by suggestion of the physician, and a tranquil, hypnotic state induced. Apomorphin is a favorite remedy for speedily clearing up a hysteric paroxysm. It is an essential preliminary to dismiss from the presence of the patient all sympathizers and other unnecessary persons.

Treatment of the disease itself cannot begin too early, even *in utero*, and by surrounding the hysteric mother with a tranquil and unemotional environment much can be done before the birth of the child which shall contribute to its better-balanced nervous organization. Before the child of such a mother reaches the age of ten years, for the benefit of both it should be placed beyond her direction and control. In the education of such a child the advice of the physician should be sought and uniformly followed, and every effort made to properly train its will and emotions. Children of hysteric parentage are inclined to precociousness, morbid sentimentalities, mawkish sympathies, and abnormal sexual propensities. The successful treatment of such symptoms is in line with our modern educational methods, by which healthy out-door sports are encouraged, precepts of patriotism instilled, and

generous feelings and hopeful sentiments inculcated. The democracy of the schoolroom and playground puts the mind of the hysteric child into balance, and he acquires self-control in adjusting himself to other and healthy minds. Thus healthy ambitions take the place of abnormal self-indulgence.

No physician can be successful in treating hysteria who does not first win the confidence of his patient. A firmness that is not sternness, a kindliness that stimulates, a sympathy that offers no encouragement to emotional outbursts, an exhibition of control by suggestion are among the attributes of the physician for the successful treatment of this disease. To secure the best results the patient must be removed from home and from all the influences which have produced and which tend to perpetuate the morbid condition of the mind. Equally imperative is the employment of a proper nurse, one who can follow the directions of the physician. The so-called "trained nurse," taught to search for objective symptoms, will, by her methods of precision, furnish the patient's mind with new symptoms, and thus aggravate the disease by suggestions. Aside from suggestions by the physician in the control of an acute attack, there are no permanent results from the treatment of hysteria by suggestion. This is due to the ineffectual control which the patient has over his emotions. The "rest-cure" has value when properly managed in the initial treatment of the severe forms of the disease, but an improvement in general nutrition under any treatment that is unaccompanied by mental gain is not a cure of hysteria.

The possibility of a physical cause for a hysteric attack should be recognized, and the disturbing factor removed. Sedatives and antispasmodics are often indicated, and malnutrition will call for the usual tonics. Hydrotherapy is enjoying not too much distinction for its beneficent effects in treatment. Hypnotism, electricity, extreme shock, and vile drugs can offer no other than a temporary relief through the patient's extreme susceptibility to suggestion. Surgical procedures, especially upon the generative organs, except for the purpose of restoring a pathologic condition, are unscientific, and it is well contended that not a single cure is recorded as the result of removal of healthy sexual organs. The one bright, particular ideal to which all methods for the treatment of hysteria tend, is to secure in the patient a fixed resolve to accomplish some unselfish purpose. The physician and the nurse, ever on the alert for the manifestations of such a purpose, will encourage its development by every means in their power, knowing that an active spirit working outside of introspective and morbidly selfish aims has no room for the development of hysteria.

THE LOCAL MEDICAL SOCIETY; A PLEA FOR ITS BETTER SUPPORT.[1]

BY GEORGE L. RICHARDS, M.D.,
OF FALL RIVER, MASS.;
OTOLOGIST AND LARYNGOLOGIST TO THE FALL RIVER AND EMERGENCY HOSPITALS.

WHY have a medical society? What is the end in view; the advantage to its members and the profession of medicine? Every community in which there is a number of physicians should have its medical society, and where the number is small the physicians of the district can combine and form a district society. Physicians lead busy lives, and, as a rule, meet socially but seldom; for they never all belong to the same church, the same secret society or organization, the same club, the same political party; hence, the local medical society is about the only place where they can all meet on the common ground of interest in their chosen profession. Here all differences of race, religion, and party are laid aside and forgotten, and all meet as equals and brothers. This association one with another is invaluable. The public, always erratic and constantly changing its doctor or misunderstanding him is liable to say to another doctor something unpleasant from which jealousies and ill feelings may, nay often do, arise. At the medical society meetings many a slight misunderstanding or feeling of jealousy is readily adjusted, and two physicians, each of whom may have felt aggrieved with the other, are after a few moments of personal conversation the best of friends. The same matter discussed by the public would very likely have brought about permanent estrangement.

We have all heard remarks like the following: "Dr. A. played me a mean trick in that case." If asked, "Have you seen Dr. A. about it?" the reply is, "No, we have not met since." Ten to one if the two men are regular attendants at the local medical society meetings one or the other will refer to the incident the next time they meet there, and after a few minutes' conversation each will be satisfied. I firmly believe that most of our differences with one another arise entirely from misunderstandings, frequently helped by our patients, who often misquote medical men. Their reply to the question, "What did the doctor say?" should always be taken with some reservation. This is due to ignorance of medical matters rather than to deliberate intention. Then it is so easy to blame the man who is not there, especially in the presence of another physician. We often hear it said that physicians never agree. While the remark is not strictly true, there is something of truth in it. Under the influence of the medical society there comes more and

[1] Read before the New Bedford Medical Society, October 17, 1898.

more of agreement, since close association is bound to make us know each other better, heal the wounds and make us all mutually helpful. We could not say of a brother member with, it may be, a shrug of the shoulders, "I do not know him," letting our auditor infer what he pleases.

To the man just entering the profession the medical society is of great benefit. He is loth to join it, because he feels overshadowed by Drs B., C., and D., whom he regards with some awe, combined with fear as to what they may say if called to see one of his patients. He joins the society and reads his maiden paper. Soon, it may be, our young doctor has a case which troubles him; he feels that the patient is doing all right, that his diagnosis and treatment are correct, and if only the family does not get unduly alarmed and call in another doctor all will go well. One day he is informed either that they wish Dr. B. to see the patient or he goes only to find that Dr. B. has already seen him and he is discharged. "So young, you know; we could never forgive ourselves if anything serious should happen, etc." Now what results if Dr. B. has met our young doctor, whom we will call Dr. X., in the medical society? What will he say to the mother, when she expresses her fears regarding the age of Dr. X., his inexperience and treatment? "You see, doctor, we only called him in because he was handy and we did not think there was much the matter. We always prefer you if there is anything at all serious." When this is said to Dr. B. he will in all probability answer, "Yes, I know Dr. X.; he is a member of our sociey and read a valuable paper before it the other evening. He is one of our coming young men. I am sure what he has done is all right." Whether the case goes back to Dr. X. or not makes little difference. Dr. B. has helped Dr. X. That family feels kindly toward him. The mother will tell her next-door neighbor how well Dr. B. spoke of Dr. X. and his fame will spread. Those few words of the older doctor have helped him far more than the value of the case he has, it may be, lost, as he will quickly find out. And Dr. B. has done only what he ought to have done; what, if a gentleman, he could not help doing. This is not at all a fanciful circumstance but an actuality. Of all persons in the profession the medical society is most needed by the younger members and recent graduates.

The general standard of the profession is raised by the medical society and members are sometimes kept by it from doing things they might under other circumstances be tempted to do. Each physician should have the honor of every other member of the society at stake. The answer to calumny would be, "That cannot be so; Dr. J. is a member of our society; he would not stoop to such a practice." All good men in the profession should be welcomed as members and made to feel that they are wanted. Carefully look up the character and attainments of members. Require that they be graduates of good schools and likely to be men of honor to the society and the profession. Do not make admittance too easy. Let character and professional attainments be the only qualifications required. Bad conduct should debar from membership and very bad conduct in members should be punished by expulsion.

To many members the paper is a bugbear and the remark will be heard, "I can not write a paper," or diffidence will be expressed as to what the older men will think about it. "Nothing to write about; no opportunities to see interesting cases," and similar excuses are offered. These excuses have no force. There is no physician who cannot write a good acceptable paper, one profitable to his hearers; no doctor who cannot carefully prepare and report a case, the discussion of which will make an interesting meeting. Take the common subjects, those that come up in daily life, and make them attractive, giving always a personal flavor to the paper. At a recent society meeting a member read a paper on acute cystitis based on his personal experiences with the disease as patient as well as physician. The ailment is a common enough one, yet an interesting discussion followed and points of great practical benefit not often found in the text-books were brought out. The youngest graduate can bring something of the latest methods as taught in the schools while the older members can give from the rich storehouse of their experience. Avoid a text-book style. Study the subject thoroughly, and the more work put on it the better, then write the paper in your own language and in your own way, making it your individual paper. Write in advance of the time needed; better work is done and there is no hurry at the end. There is usually no excuse for a hurried or poorly prepared paper, since the assignments are always made a sufficiently long time in advance. "I did not know until yesterday that it was my turn to read" is no excuse. Make the paper as good as you can. You will be pleased if you have an audience worthy of yourself and your subject. Never regret the time spent in preparation whether the audience present is large or small. The preparation has always done the author more good than it has any of his hearers. The chances are that he knows more of the subject about which he has written than he ever did before.

And as you will be disappointed if there are but few present when you read, remember that the same thing will hold true of the other man when he reads,

hence, it is your duty to be present if possible at every meeting. Physicians are busy men, nevertheless, it is my opinion that the great majority of the members of any medical society could be present at every meeting if they chose to make a little effort. Neither distance, engagements, nor any other of the numerous excuses offered would interfere with their coming if they really wanted to come. Frequently the busiest men are the most regular attendants. Granted that every member will occasionally have to be absent it is, nevertheless, true that a medical society meeting at 8.30 P.M. ought to be able to get together the greater portion of its members at each meeting. A good attendance adds to the enthusiasm and helps very much in making the meetings a success. When papers are read a full and free discussion adds to the profit and the interest. The reader would prefer to have his paper freely discussed even if radically disagreed with. Fifteen minutes spent in looking up the subject preparatory to the meeting would make every member familiar with it and a meeting which might otherwise have been dull becomes entertaining to everybody.

Whether a permanent room shall be hired, journals taken, or an attempt at collecting a library be made, will depend on the number and desires of the members. Whatever the dues they should be kept paid up. It is the only fair way and the effect on the society of members in arrears is bad.

It may be objected, "It is not worth the cost." "There is nothing I can learn from those men." To this I would reply that it is well worth the cost for social and companionship reasons alone; it is worth the cost to know each other better; and for scientific reasons it is worth the cost. Economize somewhere if need be, but never stay away from the medical society because of the cost of membership. As I recently heard it expressed, "A physician who can get no good out of the medical society is either way above or way below the average of his fellows." "I can read better papers in the journals." Granted; and yet there is a life and a fire to a paper read by its author which is lacking when the same is read in print. Furthermore, we ought to be ambitious to write as good a paper as any one else.

Competition in medicine becomes keener every year and the struggle for existence harder. The survival of the fittest is bound to come and the laggard will be left behind. The medical society is a means of keeping ourselves in the van, in the fore most ranks of the profession.

Enthusiastically supported by its members, the regularly attended medical society is a post-graduate school always in session and of inestimable value to its members.

CLINICAL MEMORANDUM.

MYOTONIA CONGENITA (THOMSEN'S DISEASE); REPORT OF A TYPICAL CASE.[1]

BY GEORGE J. PRESTON, M.D.,
OF BALTIMORE, MD.;
PROFESSOR OF NEUROLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF BALTIMORE.

THIS interesting and rare affection was first clearly described by a German physician, J. Thomsen, about 1876.[2] Prior to this, cases of what must have been this affection were described by Sir Charles Bell, Benedict, and others, but these descriptions were imperfect and somewhat vague, and it was not until Thomsen's paper appeared that the disease was clearly differentiated from conditions of muscular cramp. In studying the literature of this disease many cases must be rejected if one follows the original description of Thomsen. A large number of the recorded cases, as Jacobi has pointed out,[3] are either cases of organic disease of the nervous system or instances of what this author calls "myotonia acquisita," and have nothing in common with the congenital form of the disease as it was first described. I regret that the following report is not more complete, but the patient was sent to me from another State, and I had no opportunity to study the case as I would like to have done.

Mr. H., aged twenty-one years, consulted me in March, 1898. He looked perfectly healthy, and an examination failed to reveal disease of the thoracic or abdominal viscera. He complained of slight dyspeptic symptoms and some headache. The urine was normal. He had had the usual diseases of childhood. His mother was nervous and subject to neuralgia. She had had some sort of "cramps" just before the birth of the patient, but they did not continue long. Her father died of "paralysis"; her mother had lived to the advanced age of 102 years. The family of the patient's father was exceptionally healthy. As far back as he could remember the patient had had cramps in his muscles whenever he made any sudden movement. His father, who was with him, corroborated this statement, saying that this condition of muscular cramp has been present from the time that he had begun to make voluntary movements. He had never been able to indulge in games with other children, for, upon any sudden exertion, the cramps would come on. If he began to run the cramp would seize the muscles of his leg and he would fall. When he doubled up his fist it was some seconds before he could open his hand. When he grasped my hand he did so with force, but was not able to let go for some seconds. When he wrote he found it difficult to let go of the pen. If he suddenly extended or flexed the leg the muscles contracted strongly, though without pain, and it was only after several seconds that the muscles relaxed. If he closed his eyes tightly he could not open them at once. He said that if he looked fixedly at an object his eyes became "set," and he could not read long at a time. At times his eyes rolled up to such an extent that only the

[3] *Jour. of Nervous and Mental Diseases*, vol. 25.

whites were visible. The abdominal muscles were also involved.

Examination of his nervous system showed normal strength and no muscular atrophy; on the contrary, the muscles were unusually well developed. There was no disturbance of sensation. The reflexes, superficial, deep, and pupillary were normal. Examination of the eyes showed the discs and retinæ to be normal. The muscular spasm was not brought on by mechanical stimulation of either muscle or nerve. The electric examination could only be made once, and showed the reaction to the faradic current much below normal, while the reaction to the galvanic current was increased, and the anodal closure was distinctly stronger than the cathode closure. I was not able to demonstrate the peculiar slow contraction of the muscles to the faradic current.

The patient thought that his condition was rather worse in wet weather, but he had never had any rheumatic symptoms. His condition had remained practically unchanged, though he thought that during the past few years he perhaps had been a little worse. The various points in the history were corroborated by his father.

It will be noted that these symptoms had been present since birth, and that there were no other members of the family similarly affected. The symptoms described as "cramps" which affected the mother before the birth of the patient should be disregarded, since they did not persist any great length of time, and probably would not have been noticed but for the subsequent development of muscular spasm in her child. The question of heredity is an interesting one; undoubtedly in some cases there is a marked hereditary predisposition to the disease. In Dr. Thomsen's family, for example, all four of his grandfather's children were affected, two markedly, two slightly. Of thirteen children borne by his mother, seven were affected, and four of his five sons were subjects of the disease. Other cases of either direct or indirect hereditary influence might be mentioned. More often the disease seems to show itself in several members of the same family without any distinct heredity. Again, as in the case here recorded, the affection may appear in only one member of a family. Such a comparatively short time has elapsed since the recognition of the affection that it is impossible to speak definitely as to the heredity, since the parents or grandparents of the subjects whose cases have been studied might have had the disease without its having been recognized.

The symptomatology, which is well illustrated in the case reported above, consists in a rigidity, remaining for some seconds after voluntary contraction of the muscles. The arms and legs are most often involved, but almost any of the muscles may participate. In my patient the abdominal muscles were affected, though not to as great an extent as the muscles of the extremities. The muscles of deglutition, micturition, defecation, respiration, or parturition do not seem to be involved in any case of the disease. The muscles may be of normal size, or there may even be an apparent slight hypertrophy present. The contraction is usually much worse after a period of rest; this was very noticeable in the case of my patient. The reflexes are unchanged, and there is no disturbance of sensation. In the pure cases of Thomsen's disease there are no symptoms pointing to an involvement of the nervous system. As has been remarked, when the nervous system is distinctly involved the case is not to be regarded as belonging to the form here described. The faradic aud galvanic excitability is normal or nearly so when the stimulus is applied directly to the motor nerves, but markedly increased when the current is applied directly to the muscles. Erb describes a peculiar undulating contraction following the application of a strong faradic current to the muscles. The same rule holds with regard to mechanical stimuli, namely, normal when applied directly to the motor nerves and somewhat above normal when applied to the muscles.

The etiology of this affection is very obscure; it is certainly a family disease and probably has also a more or less marked hereditary tendency. Males are more often affected than females. The prognosis, judging from the recorded cases, is uniformly bad. No case of recovery has been reported, though there would seem to be no special danger to life. Much interest centers around the pathologic findings, since the point to be decided is whether this is a disease of the nervous or the muscular system. The only autopsy that has been reported is that performed by Dejerine and Sortas, and as Jacobi points out, this autopsy was far from satisfactory, since the patient in addition to the myotonia had several other complications. In a number of cases, however, bits of muscle have been excised and examined. In general, the muscle-fibers in myotonia congenita are from two to four times the normal size; the border of the fiber is curved and the nuclei of the sarcolemma are increased. It has been noted, also, that the transverse striation is markedly indistinct. Jacobi has noted a "massing together of sarcous elements, and a correspondingly coarse appearance in some parts of the muscle, while in others the elements are minute."

Some authors have claimed that there is a distinct psychologic element in the symptomatology of this affection, but this observation lacks confirmation. In my case there certainly was no trace of mental enfeeblement. In the absence of any findings in the spinal cord or brain, together with the lack of symptoms pointing to brain or cord lesion, it seems to me the disease should be regarded as a faulty evolution of the muscular fibers. This view is in part confirmed by the fairly constant changes which have been observed in the excised muscle. It is interesting to observe the similarity which exists between this disease and muscular dystrophy. In both diseases there is a hereditary or at least a family tendency, both present somewhat similar changes in the muscle, and in neither would there seem to be any primary lesion in the brain or spinal cord. The various therapeutic measures which have been empirically suggested have never proved of the least value.

Hospital Appointment.—Dr. R. G. Wiener has been appointed visiting-physician to the Harlem Hospital, New York.

MEDICAL PROGRESS.

Remissions in Epilepsy.—SINKLER (*Jour. Nervous and Mental Dis.*, August, 1898) has collected reports of twenty-four cases of idiopathic epilepsy in which there were remissions varying from two to twenty-nine years. All of these cases occurred in his own practice and that of a friend, and in a hospital upon which he was in attendance. The consideration of these cases in which, after prolonged intervals, even as long as twenty-nine years, there has been a recurrence of the disease, forces one to the conclusion that it is not justifiable to consider any case of epilepsy cured, no matter how great has been the interval of freedom from attacks and appearance of normal health. Notwithstanding this unfavorable conclusion, the study of these cases brings out a fact which is satisfactory, for it shows that remissions of many years' duration may occur, in which the patient is in normal health, and is able to pursue his life as if he had never suffered from epilepsy.

Removal of the Whole Stomach for Cancer.—RICHARDSON (*Boston Med. and Surg. Jour.*, October 20, 1898) removed the whole stomach of a woman aged fifty-three years, who had for one year given evidence of cancer of the stomach. There was no ascites, and the tumor at the time of operation was plainly felt. Upon opening the abdomen it was seen that a considerable part of the stomach was involved, and but for the brilliant successes of Schlatter and Brigham removal of the tumor would have been abandoned. Examination showed that the duodenum could be brought to the esophagus, and as the disease was limited to the stomach, total gastrectomy seemed to be justifiable in this case if it ever is. The omentum was first divided and tied, exposing the posterior gastric wall. The duodenum was divided after it had been tied at the pylorus to prevent the escape of gastric contents. The attachments of the lesser curvatures of the stomach were tied and divided, and finally the stomach was cut away from the esophagus. The bell-shaped opening was too large for the opening into the duodenum, and was reduced by a few interrupted sutures. There was some difficulty in bringing the duodenum and esophagus together so that the attachments of the duodenum had to be partially divided. There was very little shock after the operation, and no vomiting, although considerable gas was raised. The patient began to take water by mouth on the second day, milk on the fourth day, egg on the sixth day, and after that a liquid diet. The recovery was apparently perfect. Two months later there was no evidence of recurrence, and a drawing sensation in the epigastrium, which had caused a slight stooping, had entirely disappeared.

Richardson thus sums up the problem which a patient with such malignant disease has to consider:

1. The suffering incident to the disease. (This may vary between discomfort and unendurable pain.)

2. A hopelessness and mental depression to which death is in many instances preferable.

3. Certain death.

If subjected to a radical operation the patient has before him:

1. The dangers and sufferings of a surgical operation. (But, though the danger is great, the suffering may be no greater—it may even be less—than the suffering incident to the disease.)

2. Hope and elevation of spirits instead of mental depression and despair.

3. A fair chance of a recovery that may be permanent, though recurrence may be the rule.

A careful consideration of this question in favorable cases leads to but one conclusion, namely, that the greatest good will follow reasonable surgical interference. The chief arguments against radical measures seem to be in the necessarily great dangers of the operation, and the uselessness of deliberately incurring them. Certainly, no method of treatment is justifiable which is useless. But the operation in suitable cases is by no means useless, as shown (1) by the lessening of suffering and the prolongation of life, facts observed by physicians and friends, and (2) by the satisfaction expressed by the patient himself.

Cure of Obesity by the Method of Schweninger.—ROMME (*La Presse Med.*, October 29, 1898) describes some remarkable cures of obesity according to the method employed by Schweninger at Baden Baden. Twenty pounds lost in five weeks, fifty pounds in eight weeks, and one hundred pounds lost in nine months, is given by an observer of this method of treatment. The effect upon the heart was most beneficial. Those patients who were afflicted with weak and irregular hearts on account of the excess of fat, and who had taken digitalis for long periods on this account, were able to take long walks without fatigue, the pulse became regular and strong. The relief of sleeplessness was another benefit derived from the treatment. The treatment is based on the simplest therapeutic resources, viz., abdominal massage, warm baths, and a suitable diet, but they are administered in a truly remarkable way. The massage is given three times a day, before each meal, with the patient lying in a relaxed condition with the knees flexed. It lasts for twenty minutes and is divided into three portions. The first part is taken up with prodding the epigastric region with two fingers while the patient draws long breaths. The force used by the operator is at first slight, but is gradually increased until as much power is applied as he has. It is painful for the patient, who is able to draw only four or five breaths. Later, however, he becomes accustomed to the exercise, and can draw twenty. The second part of the séance is the pinching. The operator takes up masses of the abdominal fat and crushes them between his fingers. This part is extremely painful and amid the cries of the patient is continued until there are numerous ecchymoses all over the abdomen. The operator next buries his knees in the epigastric region of the patient, placing his whole weight upon them, and directing the patient to take long breaths. This is considered by Schweninger the most important part of the treatment. At first a patient can only take a few breaths, but the

number increases day by day until thirty can be taken. The violent exercise of the diaphragm thus produced is said to cause the absorption of the fatty matters which embarrass its movements. As may well be supposed the patient is exhausted by these manipulations and remains upon his couch for some time. One bath is given each day, but never to the whole body. The first day the arms are put into the bath; the next day the legs, and the third day a sitz bath is given. The water has a temperature in the beginning of the bath of 100 degrees, but this is gradually increased to 120 degrees. The bath lasts twenty minutes. It makes the patient very uncomfortable until he becomes accustomed to such high temperature. By it a half-hour more or less of sleep is induced.

The diet is equally remarkable. The food is served up on doll's dishes, and is taken by the patient in his own room every three hours beginning at 7.30 A.M. and ending at 7.30 P.M. Only lean meat, eggs, vegetables, cheese and fruits are allowed. The patient may not drink at meals but after each meal he may take a swallow of a mineral water from a minute glass, amounting in the whole day to a little less than a pint. Articles which are forbidden are bread, cake, butter, and all the fats, sugar, coffee, tea, milk, wine, beer, and liquor. The constipation which is set up by this regimen is relieved by aloes or an injection of glycerin. Sunday is observed as a day of rest, and the patient receives no treatment and may go into the city and live as he pleases. If he indulges in hearty living, however, he finds his weight increased by two or three pounds on Monday morning, so that excesses of that sort are not likely to be repeated. The time required to effect a cure is usually from six to eight weeks.

One Hundred Cæsarean Sections.—LEOPOLD AND HAAKE (*Centralbl. für Gynak.*, November 5, 1898) give the results of all the Cæsarean sections which have been performed in the Dresden Woman's Hospital since 1883. There were seven deaths in seventy-one cases, only four of these being attributable to the operation. Porro's operation was performed twenty-nine times, with three deaths, making a mortality for the whole series of 5.2 per cent. The authors emphasize the importance of making a careful examination for gonococci before performing Cæsarean section. In this series of cases four children were lost. Twice rupture of the uterus occurred before operation, but in each instance the mother and child were saved. In one-half of the cases there was no fever during convalescence. Thirteen of the patients developed septic symptoms. Five of the ten deaths were caused by sepsis or suppurative peritonitis.

Recurrent Dislocation at the Shoulder-joint.—FRANCKE (*Deut. Zeit. für Chir.*, vol. 48, p. 399) reports upon the pathologic condition of eighteen cases of habitual dislocation of the shoulder, a part of the material being examined at operation, and a part at autopsy. The condition most frequently found was that of hydrops of the joint. Alterations in the bones involved in the joint held the second place. The following list shows the frequency of occurrence of the various lesions: Dilatation of the capsule, 16; communication with the subscapular bursa, 1; rupture of the capsule along the glenoid, 3; rupture of the deltoid, 4; rupture of the deltoid with fracture of the greater tuberosity, 1; defects in the head of the humerus, 12; defects in the glenoid, 9; foreign bodies in the joint, free or attached, 5; foreign bodies complicated with hydrops, 2. The defects on the head of the humerus were often of a typical sort, namely, a groove on the posterior side of the head of the bone, to the inner side of the greater tuberosity. Such a defect has been variously interpreted as due to the breaking off of a fragment of bone, and to wearing from abnormal pressure. That the former sometimes happens, is shown by the occasional presence of the fragment of bone, but the correct explanation in most cases is undoubtedly that given by Koenig. He said that if a part of the head of a bone was subjected to a contusion, it could be absorbed by subsequent inflammatory processes. Hence the name, "osteochondritis dissecans," which he applied to it.

In fifteen of the cases reported operation was performed as follows: Nine times resection of the head of the humerus; five times opening of the capsule which was subsequently sutured or drained; and once infolding of the capsule without opening it. Resection of the head of the bone prevented future dislocation, but often affected the mobility of the joint and is therefore to be avoided. A better treatment consists in exposing the capsule, and then taking a tuck in it, or opening it and resecting a portion of it, or removing from the joint any foreign body together with suture of any muscle which has been torn from its attachment. The joint should be kept quiet for at least two weeks, with drainage or tamponade in order to secure the utmost possible retraction of the soft parts.

THERAPEUTIC NOTES.

For Pain Following Extraction of Teeth.—This pain, which is often severe and more or less persistent and rebellious to treatment may be soothed by the introduction into the alveolar cavity of a bit of absorbent cotton saturated with one of the following solutions:

1. ℞ Chloroformi, Spiritus, Tinct. aconiti aa . . . . *m.* lxxv
   Morphinæ . . . . . gr. i.
   M. Sig. External use.

2. ℞ Spiritus . . . . . ʒ ii
   Chloroformi . . . . . ʒ iv
   Etheris . . . . . *m.* lxxx
   Camphoræ . . . . . ʒ i
   Tinct. opii . . . . . *m.* xxx
   Ol. caryophylli . . . . *m.* viii.
   M. External use.

Hot applications to the cheek may also afford relief, or painting the gum around the painful points with the following:

℞ Menthol . . . . . gr. vi
Tinct. aconiti . . . . gtt. xx
Chloroformi . . . . . *m.* c.
M. Sig. External use.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed *exclusively* to THE MEDICAL NEWS will after publication be liberally paid for (accounts being rendered quarterly), or 250 reprints will be furnished in place of other remuneration. When necessary to elucidate the text, illustrations will be engraved from drawings or photographs furnished by the author. Manuscripts should be typewritten.

Address the Editor: J. RIDDLE GOFFE, M.D.,
No. 111 FIFTH AVENUE (corner of 18th St.), NEW YORK.

SATURDAY, DECEMBER 31, 1898.

THE PRESIDENT OF THE BOARD OF HEALTH AND THEORIES OF DISEASE.

PRESIDENT MURPHY of the New York Board of Health said in a "public statement" on "so-called grip, or whatever it might be called, either influenza or anything else."

I should like to have the opinion of these scientific gentlemen who now talk so freely of grip and other diseases whether they have ever thought of the effect of the asphalt pavement that so poultices our streets, what those effects are? A heat oozes from the asphalt pavement in summer and it becomes soft. Have the physicians of New York ever investigated that, and if it becomes soft and odor arises from it then, what are the effects of it in winter?

We would humbly submit that it is a condition, not a theory, that the President of the New York Board of Health has to face. The cases of epidemic disease that are at present so rife in New York City may not all be grip. We expressed our views editorially on that matter last week. The daily papers were certainly over-hasty, from a medical standpoint, in their announcement of the prevalence of grip epidemically and their scare headlines were of a nature to do New York serious commercial injury. We are, however, without doubt, in the presence of an epidemic or series of epidemics of contagious or infectious disease, call it what one will. This is partly due, we are sure, to unfavorable meteorological conditions which have obtained unseasonably. The absence of the accustomed amount of sunlight and the presence of superabundant moisture has given an impulse to bacterial growth, not only in numbers, but in virulence. This increase in number and virulence of pathogenic bacteria, however, is not all due to the weather alone. The condition of our streets is undoubtedly an important factor in the matter. There are streets from which the snow which fell nearly a month ago is scarcely yet entirely removed. We would suggest that the President of the Board of Health of New York City could, under these circumstances, put in his time better than in suggesting, in questionable English, subjects for doctors to theorize about. He might turn some of his intellectual acumen and ability to ask questions to questioning the Street-cleaning Department of this city as to why our streets are as they are. He might turn some of the forces of the Health Department over to the Street-cleaning Department to help clean the streets. It would be very properly within his province of caring for the health of New York City, for the Street-cleaning Department seems unable to do its duty in protecting the city's health. Or he might begin proceedings against the Street-cleaning Department for maintaining a nuisance or any one of one hundred and one other things. Only let him do something, not talk.

STUDY MEDICINE AT HOME, $2 A MONTH.

EVERY man is said to be either a fool or a physician at forty. There will evidently be no reason hereafter for him to wait until that advanced age, since for the moderate sum of $2 a month he may become both, long before that time. Two dollars a month is not much to pay for the acquisition of so much knowledge. Crocheting and farming and poultry-raising and fancy work and languages and literature and engineering are all being taught by mail *at home*, so why not medicine? After the student considers that he knows enough, and it does not take long to acquire that felicitous condition when one is learning by mail and at home, and has acquired experience by practising, we suppose, on the members of the family circle why then he may purchase a diploma. There are States where it will not be difficult for him to legitimately begin practice, and

others where he will acquire a practice all the sooner if there is an air of irregularity about him.

It is a matter for sincerest congratulation, however, that an end to this sort of thing does not seem far off. There is an interest being taken in medical organization that will finally lead to the suppression of quackery. Much remains yet to be done and the interest manifested leaves much in general to be desired, but everywhere now there is at least the recognition of abuses; the means for their suppression will surely be found. Let us hope that the signs of the times are not false and that the hour is not distant when every practitioner in the country will feel that he is ready to make some personal sacrifice for the abolition of quackery. When that moment arrives the death-knell of this blatant medico-mimicry so obtrusively demanding attention all around us will have surely sounded.

SOCIETY AND EARLY CLOSING.

SOCIETY in two of our large Eastern cities has resolved, it is said, to make an effort to bring balls and social functions generally to a close some hours before dawn. As medical men we cannot but congratulate the "goddess that makes for fashion," on this wise indulgence and remission to her devotees of their exacting duties. How much of nervous exhaustion and early degeneracy in certain classes of people, is due to the evil of turning night into day only the medical profession really knows. In a not distant city the evil is said to have reached such a pitch that when, by some chance, the special bit of femininity in which a young man is interested goes home early from a ball, say at 3 A.M., he stands on the curbstone, after having comfortably stowed his divinity and her chaperon in their carriage, and, unwilling to go back "where she is not and but now was," wonders within himself whatever shall he do with the evening that has been thus ruthlessly broken in upon.

Nature is a good usurer. She lends of the vital treasure stowed away almost whatever we ask, but she collects the debt mercilessly and charges a high rate of interest. Abuses like this in the matter of sleep are drafts on life due ten or perhaps twenty years after date, but then without grace. Metaphor aside the evil is a serious one. Many a failure in business, many a breakdown in young lives, is due to the unreasonable demands of senseless fashion.

We plead for shorter hours for the overworked devotees of fashion with as earnest a humanitarian purpose and as serious a feeling of sincere pity as we do for the workman and workwoman called upon to spend too long hours at their daily toil.

HIPPOCRATES AND CURATIVE INJECTIONS OF GAS (AIR) INTO THE PLEURAL CAVITY.

IN reference to priority in the use of intrapleural injections of gas of some form, as discussed in our issue of November 12th, a correspondent, Dr. J. F. E. Colgan of Philadelphia, calls our attention to the following condensed quotation from Hippocrates, as it occurs on page 263 of the "Epitome of Hippocrates and Galen," Coxe, Philadelphia, 1846, under No. LVIII.: "The lungs falling on the pleura (?). It arises sometimes from a wound or from the operation for empyema; singular treatment for, by introducing air into the cavity."

The quotation is an epitome, and not a very lucid one of chapter xxiii of the second book "On Diseases," which may be found in its entirety in Volume III. of Haller's (Lausanne, 1784) edition of Hippocrates' works. Under treatment of *pulmo in latus decumbens*, retraction of the lung (we suppose), occurs the passage: (If the lung should retract) after a wound or after section for empyema (*purulento secto*), then a bladder being fastened to a tube should be filled with air and introduced, being closed by a solid pencil of tin fastened to it and allowed to protude. Just what the idea of this method of treatment was he does not say. With its results he seems to have been perfectly satisfied, for he adds: "This method of treatment will give the results you desire."

It would be most interesting could we have some data of Hippocrates' cases treated by this method, for the treatment of traumatic pneumothorax or empyema in our day is not so perfect but that we would be ready, if they promised good results, to receive suggestions even from Hippocrates. As to the question of priority of idea in intrapleural injections, the probability is that under the circumstances a court of patents would be apt to decide that the ancient scientist has not so completely com-

passed the principle, in the matter of setting the lungs at rest for therapeutic purposes, as to render the idea legally unpatentable by an enterprising modern who had rediscovered it. This is said in simple justice to the modern inventor. It is to be hoped, however, that our German confrères will not seize upon the suggestion and forthwith proceed to secure American patents. .

In this connection the fact must not be lost sight of that the merit of discovering a new and useful application of principles previously enunciated but unapplied and forgotten is quite as great as that of him who first conceived it.

MASSAGE BY TRAINED NURSES.

IT is quite probable that the trained nurse, during the time spent in hospital service, finds her hands very full, and would rebel against the extension of her curriculum by so much as a jot. She is hard-worked all day and is little inclined, according to our experience, to sit through didactic lectures or theoretic talks during the evening. But those who have the most vital interest of the correct training of nurses at heart and who employ them in their post-graduate work have a right to expect efficiency in certain directions which is unfortunately lacking in many nurses at the present day. If the trained nurse is really the "handmaid of medicine" she should be able to carry out all the instructions of the physician without a resort to outside aid.

In view of the increasing favor with which massage is regarded as a curative factor in many cases, as a necessary measure in others, it has become essential that the trained nurse shall be able to execute this measure in accord with scientific principles and in harmony with physiologic needs. The hours endured by the young women in our hospitals acquiring the merest smattering of anatomic terms, physiologic complexities, and the doses of unused drugs might well be spent in the practice of massage under the instruction of a competent teacher. It would by no means be regarded as a superfluous accomplishment for the trained nurse properly to carry out massage treatment, but would further the usefulness of this eminently useful young woman. Again and again it happens that a family is able to stint itself sufficiently for the employment of a competent nurse, but does not command resources great enough for the additional service of a *masseuse* when this proves necessary. Economy and convenience in general demand that the trained nurse shall be able to perform this function; nothing that she may be able to do to further the recovery of a patient and to assist the physician in this purpose is superfluous. Among the important elements tending toward these ends is massage.

DOCTORS' PROTESTS NOT ALL IN VAIN.

SOME three months ago one of our foreign correspondents called special attention to the fact that the Congress of Slavish Naturalists and Physicians would not be held at Posen this year as announced, because of the prohibition, by the Prussian police department, of the attendance of foreigners. As this police regulation would exclude the Russians, the Poles and the Czechs, who form the great majority of the usual attendants at the Congress, the meeting was postponed until 1900, when it will convene at Cracow in Austrian Poland. As our correspondent noted, the decree of the police excluding Austrian subjects from attending a scientific congress in the supposedly fraternal territory of a member of the Triple Alliance had been the occasion for vigorous protests and representations to the Austrian Government on the part of the Czechish and Gallician physicians who had expected to attend the Congress.

The result of these protests has become apparent in some recent head-lines in the daily press, "The Triple Alliance in Peril," "Austria Threatens to Withdraw from the Triple Alliance," and the like. The ostensible motive for the formal declaration of the Austrian Prime Minister before the Imperial Parliament "which fell like a thunderbolt on the Germans," is the fact that Prussia has been expelling numbers of Austrian subjects from her dominions because they are Slavs. This expulsion of Austrian Slavs has been going on for years, and it is noteworthy that the vigorous Austrian protest in the matter should come only three months after the Prussian insult to the Slavish scientists and medical men. The handwriting on the wall is not hard to read for one who knows something of political conditions among the Slavs and who realizes that the great apostles of the new Pan-Slav movement among the Czechs, the Poles, and the Russians have been the members of the medical profession. The au-

thority and respect which their position among the people gives them has been used on every possible occasion for a zealous propaganda of the new Slavism and the dissemination of ideas that would lead their fellow countrymen to claim the racial prerogatives to which their numbers entitle them. The Prussian Government tackled a hornet's nest when it saw fit to impugn the motives of the Slav scientists and physicians who were to meet at Posen, and assumed that their object was a political one. Our foreign correspondent said at that time that the final result of that interference was not yet in sight. The present conjuncture justifies that prophecy. Meantime there is a lesson for the physicians of all nations in the present situation. It seems to read "In union there is strength."

ADVERTISEMENT OF ABORTIFACIENT REMEDIES.

THE trial of the parties who, after selling abortifacient remedies in London, endeavored to blackmail their customers, the threat of legal prosecution "for the awful crime of attempting to bring about abortion or prevent birth being hung over them unless they forwarded ten dollars," has brought with it some very interesting developments. The judge who is trying the case announced during the progress of the trial that newspapers publishing advertisements of remedies that were, or were evidently meant to be considered, abortifacient in their action were amenable to legal prosecution as "accessories before the fact." This is a decision of the widest significance and has had an immediate practical application in England. Our London correspondent in his letter published December 24th, announces that the London police department have issued a public notice, that in future all newspapers inserting such advertisements, after one warning, will render themselves liable to prosecution for inciting to crime.

It is utterly disingenuous to argue that such advertisements are printed by newspapers in perfect good faith and with the sincere belief that they are only calling public attention to certain very proper emmenagogues. If proof to the contrary however were required it would be found abundantly in the fact that, in England at least, such advertisements are accepted at, not two or three, but sometimes four or five times regular space-rates for ordinary legitimate advertising. Doubtless the same state of affairs would be found to obtain in this country if the advertizing managers of some of our abortifacient publishing journals were consulted. It is, of course, well understood, at least by medical men, that none of the much-lauded abortifacients ever produce the result looked for, despite the testimonials to that effect, sometimes published. That, however, only adds the crime of selling under false pretences to that of inciting to crime.

The English have in this matter evidently hit upon the solution of a most difficult and disgracefully manipulated question. We call attention to the methods they employ and the legal principles upon which their proceedings are founded in the hope that our medical societies in this country may be encouraged to do something for the remedy of a glaring evil that disgraces our American journalism. May we be able to chronicle before the end of the year that is just upon us, some steps in this matter looking to the correction of the abuse.

ECHOES AND NEWS.

Six Convicts Made Insane.—Six convicts, driven mad by idleness, were recently taken from the Kings County Penitentiary to asylums for the criminal insane. One of the penitentiary officials said that until the abolition of convict labor there had not been a case of insanity in that institution for years.

The New York State Medical Society.—The cheering news comes from the Business Committee of the New York State Medical Society that the program for the next meeting is already overflowing with contributions, and that no more applications for positions on the program can be entertained.

Christian Scientists Convictions.—For the second time within two weeks, a Cincinnati, Ohio, jury has convicted, and a Cincinnati judge has fined, a practitioner of "Christian Science," who had been arrested on the charge of violating the State law which forbids any but duly licensed doctors to treat the sick for hire.

Many Kiss the Relic of St. Anthony.—At the Catholic church in East 113th street, between Second and Third avenues, New York, the sacred relic of St. Anthony of Padua (a portion of the thigh bone) has been exposed and is being kissed by hundreds of people. Among these people are many deaf, dumb, blind, and lame who hope for relief.

Clinics at the Skin and Cancer Hospital, New York.—Dr. L. Duncan Buckley has inaugurated a series of clinics on diseases of the skin, every Wednesday afternoon, at the New York Skin and Cancer Hospital, beginning at 4.15 P.M. The course is free to the medical profession.

Clinical material is abundant, the facilities for such work are excellent, and the accommodations for spectators and patients most comfortable.

Bubonic Plague on a British Steamer.—The report comes from Plymouth, England, that there was a case of bubonic plague on board the British steamer "Golconda," which arrived from Calcutta via Mediterranean ports. The patient was one of the cabin passengers, an officer in the India Company's service, who was coming home on leave. He was attacked by the disease the day after the steamer left Marseilles, and was isolated as soon as the nature of his disease was learned. He was landed in Plymouth.

The Report of the New York State Commissioners of Lunacy.—This, the last annual report is a large volume made up of statistics, photographs, tables, and detailed accounts of the work of the State's twelve great hospitals and their 20,000 insane inmates. The evidence furnished seems to show that the present method of caring for the insane is, on the whole, an efficient and creditable one. Besides hospital records, this report contains other matter, notably a description of the Pathological Institute which has just been established for the scientific investigation of the nature and cause of insanity.

Advertising within the Profession.—We glean from the *Medical Press and Circular* that a series of illustrated medical biographies have been appearing in the pages of the *Dublin Lady's Pictorial.* The Presidents of the Irish Colleges of Physicians and Surgeons were persuaded to allow their portraits to appear as the first in the series. As our contemporary very justly says, "if dignitaries and titled personages are allowed to advertise themselves in this way so should the working men of the profession, and to that end all restrictions as to advertising embodied in the by-laws of medical societies should be repealed."

A Quack in Trouble.—The *Texas Clinic*, in its December number, quotes from the MEDICAL NEWS the letter of correspondence recently published regarding a Dr. Bemis of Glen Falls, N. Y. In commenting upon this the editor of the *Clinic* says: "The editor has heard of Dr. Bemis. The flattering reports of his wonderful cures, by an eminent divine of Louisiana, caused many patients to go to him from that section. Two of these unfortunates were personal friends of the editor. Each was assured of a complete cure and each was relieved of a good sum of money, but neither benefited in the least."

Dr. Adams Lectures at Bellevue.—By invitation of the faculty, Dr. S. S. Adams of Washington delivered a lecture last week before the senior class of the University and Bellevue Hospital Medical College, New York, upon the subject of "Fevers in Children; Their Significance and General Diagnostic Value, and Antipyretic Treatment." The lecture was given at the usual hour devoted to Pediatrics. This custom, inaugurated, we believe, by Professor Northrup, of occasionally inviting a prominent specialist to occupy his lecture hour, has many features to commend it. It is a pleasant and instructive experience for the medical class, it is a stimulus to the guest, and productive of a cordial feeling among all concerned.

A French Medical Hero.—A decree dated October 1, 1898, confers the cross of the Legion of Honor upon M. le Dr. Bartel, a young naval surgeon in the French service in Upper Dahomey. The brave deed for which the decoration was conferred is thus briefly described in the official record. "During the affairs of the 4th and 8th of November, 1897, while serving with the Borgan column, this officer, despising death, completed his difficult duty beside the wounded under a perfect rain of arrows." We noted last week the conferring of the Victoria Cross upon an English surgeon for a like act of conspicuous bravery. Medical gallantry knows not any narrow national limits, and the call of duty is as powerful to the French as to the British medical man, though both are attending to common soldiers and sailors in a distant foreign country and without thought of the possible distinction to come inspired only by the sense and motive of care for the wounded who looked to them for help.

The New York Eye and Ear Infirmary.—Advance sheets of the annual report of this institution show that it is accomplishing much good work, although hampered by lack of pavilions for the use of the ear and throat department and for the reception and care of patients suffering from contagious diseases of the eye. The surgical staff now comprises more than fifty. The resident house staff, clinical assistants and assistant surgeons are selected after a competitive examination. During the year ending September 30, 1898, 24,904 new patients and 42,977 patients were treated in the eye department; 818 patients, 418 of whom paid board, were received in the eye wards, and 2771 surgical operations were performed, including 178 for cataract. The Hoab magnet has proved invaluable for locating and also for removing pieces of steel from the eye. The throat and nose department treated 4947 new patients, an increase of about 500 over the former year; of these 3000 suffered from throat affections; 1136 operations were performed without any fatality.

An Unfortunate Dental Fatality.—The London *Medical Press* reports the following sad story from Australia which is probably unique of its kind. A young lady immediately after the extraction of a tooth was taken with violent cough and dyspnea which persisted in spite of all remedies until her death, which occurred two weeks later. At the autopsy a tooth was found in a bronchus; infection of the lung parenchyma had occurred, and gangrene had supervened to bring on the fatal issue. The dentist denied that he had let the tooth slip from the forceps, but the evidence presented showed that he had put the attendants out of the room and inverted the patient. This he declares he did because the root of the tooth was badly affected, pus had collected there and he feared that she had aspirated septic pus into her trachea and bronchi. It seems plain that he knew that the tooth had passed into the air-passages, since if it had merely been swallowed he would scarcely have resorted to the extreme measure he employed. For the concealment of the fact,

he is criminally responsible, since candor in the matter might have led to operation and so possibly prevented a fatal issue.

Smallpox in the United States.—It is evident from the recent report of the Marine Hospital Service that the widespread invasion of smallpox is being rapidly suppressed.

OBITUARY.

DR. JOHN B. HAMILTON.

DR. JOHN B. HAMILTON, former Surgeon-General of the United States Marine Hospital Service, and editor of the *Journal of the American Medical Association*, died at Elgin, Ill., December 24, 1898. For more than a year he had been superintendent of the State Asylum for the Insane, at Elgin, and it was within the walls of that institution that he breathed his last. While on a visit to the East two weeks ago Dr. Hamilton was attacked by a severe cold upon which a sharp attack of peritonitis supervened.

He grew worse rapidly, and on December 18th it was decided by Dr. Nicholas Senn that an operation was necessary to save the patient's life. The operation was performed, but such conditions were found as to render all chance of recovery doubtful. He rallied slightly after the operation, and for a few days there seemed to be a probability that he would pull through. During the last two days he had, however, been sinking slowly, and death came at 6:30 o'clock Christmas eve.

Dr. John B. Hamilton was born in 1847, in Jersey County, Ill., and was graduated from Rush Medical College, Chicago, in 1869. In 1874 he was appointed Assistant Surgeon in the United States Army, but resigned in 1876 to enter the Marine Hospital Service. Three years later he became Supervising Surgeon-General of that service, succeeding General John M. Woodworth. Dr. Hamilton infused new life into this department of the Government and instituted important reforms. He caused the first visual examinations of pilots to be made, and the first physical examinations of seamen preliminary to shipment. During his incumbency of office he succeeded in having the National Quarantine acts passed.

In June, 1891, when the House of Representatives failed to pass the Senate bill providing for the equalization of the salary of his office with that of the Surgeon-General of the Army and the Surgeon-General of the Navy, Dr. Hamilton resigned his commission as Surgeon-General and returned to the ranks. He was stationed at Chicago for three years in charge of the Marine Hospital service, but in 1896, rather than be transferred to San Francisco, he resigned from the service altogether. He was professor of surgery at the Rush Medical College and the Chicago Polyclinic, surgeon to the Presbyterian Hospital and consulting surgeon to the St. Joseph's Hospital and the Central Free Dispensary. Dr. Hamilton's reputation will rest especially upon the work he did while at the head of the Marine Hospital Service and his editorial labors in connection with the *Journal of the American Medical Association.*

CORRESPONDENCE.

LYCOPODIUM POLLEN IN URINE.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—To one who has not himself had the experience, the account given by Dr. George Dock in your issue of December 17th, of the difficulties encountered in recognizing lycopodium pollen in the urine will seem somewhat far-fetched, but having had a somewhat similar experience I can join with him in expressing surprise that a substance which is in such general use and which has such a striking appearance under the microscope should be so unfamiliar even to expert microscopists.

The fact that not one of the various text-books on urinary analysis even mentions the occurrence of lycopodium pollen in the urine led me to publish a note on this subject in *Pediatrics*, page 107, February 1, 1896.

M. MANGES, M.D.

941 MADISON AVENUE,
NEW YORK, December 23, 1898.

THE TREATMENT OF GRIP.

To the Editor of the MEDICAL NEWS.

DEAR SIR:—Inasmuch as the pathology of grip is still somewhat obscure and its etiology practically unknown, the treatment is naturally directed toward the relief of symptoms. While these differ widely in different patients there are nevertheless a few constant phases of the malady that have been seen in all of my cases.

In the cases that I have seen I found high temperature, full, rapid pulse, pain in the back, orbital pain, headache, muscular soreness, restlessness and insomnia, and usually constipation. So common was the last symptom that I am led to believe it a causative factor, or at least a condition necessary to the disease. The premonitory coryza of former epidemics did not appear in my cases until the other symptoms had subsided. The urine was scanty, highly colored, and of high specific gravity, but repeated examinations in twelve cases showed the presence of albumin in only one.

In lieu of more scientific treatment it seems to me that elimination by all the avenues of excretion is the rational way to attack the disease. As it is usually of short duration we need not fear prostrating measures. I order the patient sponged with alcohol, a mustard plaster placed over the seat of pain in the back, and prescribe the following:

℞	Pulv. ipecac. et opii . . .	gr. x
	Hydrarg. chlor. mitis . . .	gr. iii
	Sodii bicarb.	gr. ii.

M. Sig. Take at bed hour.

Next morning I give a tablespoonful of effervescent sodium phosphate in a glass of water and advise the patient to drink water freely throughout the day. Every two hours he is given phenacetin gr. v until five such powders have been taken. His diet is oatmeal, milk, and toast. After the acute symptoms have disappeared and there is left only a feeling of weakness, anorexia, and lack of ambition I prescribe a preparation of the alkaloids

of cod-liver oil with the malt and hypophosphites. This being slightly bitter stimulates the appetite and within a week puts the patient in normal condition.

JOSEPH ALAN O'NEILL, M.D.
118 WEST EIGHTY-FOURTH STREET,
NEW YORK, December 24, 1898.

OUR PHILADELPHIA LETTER.

[From Our Special Correspondent]

REORGANIZATION OF THE POLYCLINIC — HOMEOPATHIC STATE HOSPITAL FOR THE INSANE — THE HEBREW CHARITY BALL—PERSONAL NOTES—STATE MEDICAL EXAMINING BOARD—DIPHTHERIA CLOSES A SCHOOL—BOARD OF HEALTH NOTES — INFLUENZA—HEALTH STATISTICS.

PHILADELPHIA, December 27, 1898.

RUMORS have been rife as to changes in the management of the Polyclinic and of differences of opinion which were said to threaten the equanimity of its faculty. Consequently the announcement that the Board of Trustees which formerly contained medical men will, after January 9th, consist only of laymen, is no surprise. Dr. John B. Roberts, President of the Board, resigned this position about a month ago and Drs. Henry Leffman, Thomas S. K. Morton, W. J. Freeman, and Samuel D. Risley, members of the board, will also resign. It is stated that all concerned feel that more attention can be given to instruction, and the business matters of the institution can be more readily handled under this new régime, a step which has apparently been necessary for some time.

The Homeopathic Medical Society of Germantown, at a meeting held last week, received from Dr. Isaac W. Heysinger the report of the Committee on Organization for a State Homeopathic Hospital for the Insane. Each homeopathic society in the State is to send delegates, together with a committee from the State Homeopathic Society, to secure passage, by the next Legislature, of a bill providing for such an institution. A similar bill was passed by the last Legislature which the Governor did not sign. When it is remembered that there are now five State institutions for the insane for which it has been impossible to secure from the Legislature sufficient money to prevent overcrowding, and that there is likely to be some general opposition, it seems extremely doubtful that the bill will be passed.

The Hebrew Charity Ball will be held February 7th and the money raised, of which there is always a large amount, will be divided between various charities, among them being the Jewish Maternity Association, the Jewish Hospital Association, and the Jewish Foster Home and Orphan Asylum.

Dr. Stewart Reeser, a graduate of the Medico-Chirurgical College and formerly Resident Physician of the Friend's Asylum at Frankford, died at his home in Scranton on Friday, December 15th.

Dr. John Marshall, Professor of Chemistry, Dr. George A. Piersol, Professor of Anatomy, and Dr. Edward T. Reichert, Professor of Physiology, all of the University of Pennsylvania, have gone to New York to attend the Association of American Anatomists and the Chemical and Physiological Societies.

At the last meeting of the College of Pharmacy, William B. Thompson read a paper, entitled "Some Observations on Acetracts in Comparison with Fluid Extracts." While further clinical experiments are needed to determine their value many favorable points seem to make the employment of the acetracts a mere matter of time. Lyman F. Kebler presented a paper on the "Physical and Chemical Properties of Lithium Benzoate and Lithium Salicylate," being a continuation of his work on this subject for the Committee on Revision of the Pharmacopœia.

The State Medical Examinating Board held a meeting last week at the Lafayette Hotel to make its final decisions on the examinations of applicants for licenses to practise medicine in Pennsylvania. One hundred and three graduates took the examination, which was held early in December, and of this number three were expelled for cheating, twenty-nine failed, and seventy-one were passed by the board.

In a report submitted last Friday by Medical Inspector T. Howard Taylor to the Board of Health, it was recommended that St. Stephen's Parochial School be closed on account of an alarming prevalence of diphtheria in the school. Six deaths and a large number of cases have occurred in this school, and the board ordered it closed for twenty days for thorough disinfection and fumigation. The question of admitting medical students of advanced grades to the Municipal Hospital for the purpose of studying contagious diseases was again brought before the board, and on motion it was decided not to admit them.

Dr. Woodward, owner of the church property which is being used by the Board of Health for a case of typhus fever, has presented the church as a gift to the city. When Director Riter sanctioned its use as a means of preventing the spread of typhus among Municipal Hospital patients much criticism was indulged in, many calling it a ruse to make the city pay an exorbitant price for worthless property, and others saying that it was done to put a stop to the movement on foot to change the location of the Municipal Hospital. By Dr. Woodward's gift this movement will, incidently, be killed, and the city at an expense of $600 for fitting up beds, etc., will secure room for about thirty additional patients.

Philadelphia's death-rate has markedly increased during the past week, in which there were 169 more deaths than in the week before and 254 over the corresponding week of 1897. There were 29 deaths resulting from grip and 129 ascribed to "inflammation of the lung," many of which were no doubt due primarily to influenza. Dr. John B. Deaver is quoted as saying that he firmly believes influenza is the most frequent cause of appendicitis, producing as it does a catarrhal inflammation of the gastro-intestinal tract which leads to appendicitis. He says further that during the present epidemic he has performed two operations which he does not hesitate in stating most positively had their origin in attacks of influenza, and believes there will be an appreciable increase in the number of appendicitis cases. Many physicians incline strongly to this belief, and the present epidemic should

give us opportunities of proving or disproving this theory. The epidemic thus far seems to have been increasing by enormous strides and while the first cases were marked by their short duration and mildness, this is no longer the case.

The total number of deaths occurring in Philadelphia during the week ending December 24th, as reported at the Health Office, was 650, of which 164 occurred in children under five years of age. The total number of new cases of contagious diseases was 234, reported as follows: diphtheria, 80 cases, with 18 deaths; scarlet fever, 33 cases, with 2 deaths; typhoid fever, 130 cases, with 24 deaths.

MEDICAL MATTERS IN CHICAGO.

[From Our Special Correspondent.]

BLOOD OF TUBERCULAR PATIENTS—AMEBIC DYSENTERY IN CHICAGO—ADENOID GROWTHS IN THE PHARYNX—DONATION BY MRS. AVERELL—ANNUAL REPORT OF ST. LUKE'S HOSPITAL—PUBLIC HEALTH AT THE CHICAGO WOMAN'S CLUB—ANTITOXIN TREATMENT OF DIPHTHERIA—FORMALDEHYD DISINFECTION—INERT VACCINE LYMPH—SOCIETY FOR THE PREVENTION OF TUBERCULOSIS.

CHICAGO, December 27, 1898.

AT the meeting of the Chicago Academy of Medicine, held December 9th, Dr. George W. Johnson presented a contribution to the study of the blood of tubercular patients. He reported observations on the blood of fifty tubercular patients in the advanced stage of the disease, the diagnosis having been established by microscopic examination of the sputum. Especial attention was given to cavity formation with the idea of determining the presence or absence of leucocytosis in such conditions. The technic employed was essentially that detailed in Cabot's work on the blood. Pus micro-organisms were found with great abundance in each one of the fifty cases. Chlorosis was met with in eight cases, five of them being males. In cases of chlorosis there is lymphocytosis; in secondary anemia the adult lymphocytes are the more numerous. Well-defined necrobiotic changes were noted in thirty-six of the fifty cases. Of these thirty-six cases, twenty-eight had secondary anemia. The hemoglobin was far below normal in each of the cases; forty-five of the fifty cases had pathological leucocytosis; cavities were demonstrated in twenty-eight cases; twenty-six of these showed great increase in the number of white cells; nineteen in the remaining twenty-two also had leucocytosis, although no cavities were demonstrated. He believes leucocytosis is diagnostic of cavity formation if the vital resistance of the patient is maintained.

At a meeting of the Chicago Medical Society, December 14th, Dr. R. B. Preble reported two cases of amebic dysentery, which he said is not so very uncommon in Chicago, but the great majority of the cases are imported, so that these two cases are of interest because they were acquired in this city. He finds, by inquiry that a few practitioners have observed cases acquired here, but none of them have been placed on record. The first case was in an American, thirty years of age, a resident of Chicago for nine years. For the past fourteen months he has had diarrhea with blood and mucus in the stools, moderate tenesmus and abdominal pain. Ameba coli were found in large numbers. Improvement, but not recovery, has been observed under colonic flushings of quinin and of silver nitrate. The second patient, Mrs. C., is fifty years of age, Irish, and has been a resident of Chicago for thirty years. She had diarrhea with blood, mucus, and pus, during the summers of 1897 and 1898, with ameba in the stools.

The widow of a Chicago pioneer, Captain Albert J. Averell, has donated to the Presbyterian Hospital of this city, $50,000. The gift provides in perpetuity for ten free beds for men in the hospital in memory of her husband. Mrs. Averell's gift opens the second free ward of the hospital. The other free ward is the William Armour memorial ward, also of ten beds, endowed by Mrs. Bertha Cobb Armour, in memory of her husband. The hospital, however, has many more free beds and several free rooms. Since its organization in 1884, the Presbyterian Hospital has cared for 21,000 patients, and the daily average of its eight wards is 200 patients. The daily average of free patients for the year has been 65.

St. Luke's Hospital has issued its annual report covering sixty-five printed pages and telling what has been accomplished from October 1, 1897, to October 1, 1898. This was the thirty-fifth year of the hospital, and in the twelve months the receipts were $82,439.79, with disbursements of $81,183.89. During the year 1761 patients were treated. The greatest number in the hospital at one time was 141, February 4th. The net maintenance expense, according to the report of the superintendent, was $66,585.69.

Recently the Chicago Woman's Club discussed the matter of "Public Health of a Large City." Professor Edwin O. Jordan, Assistant Professor of Bacteriology in the University of Chicago, spoke of the need of pure water. He said that typhoid fever and Asiatic cholera are the only diseases which can be traced directly to impure water. A good way to test the sanitary condition of a community is to consider the amount of typhoid fever prevalent. Sand filtration, in his opinion, is the only effective means by which the water-supply of a large city can be purified. The efficiency of this method in freeing the water from typhoid bacteria is demonstrated by the experience of Hamburg, Germany, and Lawrence, Mass. In the latter city the death-rate from typhoid fever ranged from 105 to 134 during the six years preceding the construction of the filters. The year after the filter was put into operation the typhoid-fever rate fell to 47, and in 1897 it had been reduced to 16. Figures show that the considerable expense involved in the construction of sand filters is more than counterbalanced by the saving to the community in valuable lives, as well as in obviating the expenditure otherwise necessary in the care of the sick, etc.

In speaking of disposing of sewage he said that the problem of sewage disposal is twofold and includes, first, the keeping of the sewage out of water-supplies, and second, the prevention of a nuisance. The economic

value of sewage has perhaps been overestimated. Modern science has revealed other methods of replenishing the store of nitrogen in the soil.

Miss Marion Talbot discussed sanitary plumbing, and Dr. Sarah Hackett Stevenson spoke of public baths. Dr. Arthur R. Reynolds, our City Health Commissioner, closed the meeting with an address on the work of the Health Department, dwelling mainly upon the mortality of the city, giving comparisons for many years back. He made a feature of his address the decrease in the mortality of infants since the milk-inspection ordinance was adopted.

The Department of Health calls attention to the results of the antitoxin treatment of diphtheria. During November, 163 reported cases of diphtheria were investigated; of these 98 were bacterially verified as true diphtheria, and were treated with antitoxin. With 4 cases remaining under treatment from the previous month, a total of 102 cases were treated, with 97 recoveries, 3 deaths, and 2 remaining under treatment at the close of the month. This gives a mortality of three per cent. for the completed histories. The gravity of the cases is shown by the large number (10) requiring intubation. Of the deaths, 2 occurred among the intubations, and all 3 fatal cases were first seen later than the fourth day of the disease.

Of formaldehyd disinfection, an unusually low temperature during November afforded opportunity for demonstrating the sufficiency of the margin of safety, both as to volume of gas evolved and period of exposure in the department method of disinfection by formalin-sprinkled sheets. Special tests were made during the coldest periods—week ending 19th, mean temperature 39°, lowest 30°, and week ending 26th, mean temperature 29°, lowest 2°—in unheated rooms where the temperature was below the freezing-point. It was found that evaporation was so far retarded that the sheets were not entirely dry at the end of five-hours' exposure; but streak agar inoculations of diphtheria, typhoid, and coli-communis bacilli in inclined tubes were sterilized to the depth of one and one-half inches in this period of exposure. Beneath this point there was growth in all cases after seventy-two hours.

During the year 1897, the Department of Health distributed 126,800 tubes of glycerinated vaccine lymph to its public vaccinators, and obtained 82,804 successful vaccinations and revaccinations—an average of a little more than 1½ (1.53) tubes for each successful result. From January to May, inclusive, and in October and November, 63,600 successful results were obtained from 72,940 tubes distributed, an average of 1.14 tubes for each success, or 87.7 per cent. During the first eleven months of the present year, 75,610 tubes have been used with only 25,864 successful results, an average of nearly 3 (2.92) tubes to each success, or 34.2 per cent. During the last four months the figures have been even more unsatisfactory—45,090 tubes and only 12,124 successes, an average of 3.71 tubes each, or less than 27 per cent. Without further detail, it is evident from these gross figures that the producers of glycerinated vaccine have yet much to learn before they can be relied on to furnish a uniformly potent as well as pure lymph.

At a meeting of the Chicago Medical Society, December 21st, Dr. Arthur R. Reynolds addressed the Society on the organization of an association for the prevention of consumption and other forms of tuberculosis, the membership to consist of ordinary and of life members. Methods—the education of public opinion and the stimulation of individual initiative by means of a central bureau for the collection and distribution of information as to modes of diffusion of tuberculosis and measures of prevention; the circulation of pamphlets and leaflets setting forth in plain language the results of scientific investigation of the above points; public lectures by men approved by the Society; addresses at congresses and other public gatherings; cooperation with other societies having for their object the promotion of public health; the cooperation of the public press; the holding of periodical congresses and the issuance of an annual report; the promotion of the establishment on a self-supporting basis of open-air sanatoria for tuberculous patients; the influencing of legislatures, county and city councils, and other public authorities on matters relating to the prevention of tuberculosis. At a future meeting the president of the Society will appoint a committee for the purpose of investigating and carrying out the suggestions of Dr. Reynolds. It is well known that similar societies have been formed in Great Britain and in some of the larger cities of this country, particularly in Philadelphia.

TRANSACTIONS OF FOREIGN SOCIETIES.

THE PROTOZOA OF CANCER—SYPHILITIC LESIONS OF THE PERITONEUM — CATHETERIZATION OF THE URETERS AS A THERAPEUTIC RESOURCE — A CASE OF PAROXYSMAL HEMOGLOBINURIA — TRAUMATIC DILATATION OF THE HEART—OPERATIONS WITHIN THE PLEURAL CAVITY — LORENZ'S OPINION OF CALOT'S OPERATION.

AT the Berlin Medical Society, November 2d, JURGENS read a paper on "Protozoa of Carcinoma." He said that the previous investigations of this subject had usually failed to give practical results because they did not show the very beginning of the invasion of the cells. He had the good fortune to avoid this failure in an autopsy made upon a man aged thirty-four years, whose larger bronchi were compressed with carcinoma so that the secretions of the mucous membrane were prevented from escaping. In these occluded bronchi he found the pathogenic micro-organisms of carcinoma in all stages of growth. First, there were large spindle-shaped bodies filled with minute spores. The latter were free, had ameboid movements, and penetrated in part into the epithelial cells while in part they remained between the cells. Those spores which penetrated into the cells grew until they distended the cells. Secondly, there were granular cells with distinct cell-membranes of crescent- or sickle-shape. Third, there were cells, much increased in size, whose contents were markedly granular and whose nuclei contained nucleoli. Fourth, there were double

cells produced by conjugation in which there were two nuclei and a mild degree of granulation. Jurgens considered that the micro-organisms belonged to the gregarines.

At the session of November 9th, PICK showed a preparation from an autopsy which he had made upon a woman aged fifty-six who died from syphilis of the liver and kidneys with ascites and edema. There was amyloid degeneration of the spleen and kidneys, and what is more remarkable, of the genital organs. Moreover the peritoneum exhibited little tubercles with depressed fatty-degenerated centers. Similar syphilitic tubercles were found upon the heart. This is a condition of the greatest rarity, and it is worth noticing that the patient had been treated with mercury, and the tertiary lesions could not, therefore, have been due to its use, a claim which has been advanced by some writers.

CASPER spoke of the "Therapeutic Results Which Follow Catheterization of the Ureters." He mentioned three cases. A man aged forty was sick for four weeks with marked pain and scanty urine. The bladder was empty. When Casper saw the patient no water had been passed for thirty hours. The pulse was good, there was no fever, and no vomiting. There was no tenderness in the right loin. The rectal examination was negative. A catheter was passed into the right ureter a distance of about 5 cm. (2 inches). An obstruction, due perhaps to a stone, prevented its further passage. Fifty grams (1.5 ounces) of warm oil was injected into the ureter. Twenty minutes later the patient passed urine voluntarily, and from that time on micturition was normal. One week afterward, by means of the cystoscope, a small stone (oxalate) was found in the bladder and was crushed. The second patient was a woman aged twenty-eight who suffered after her confinement from pain in the right side. The urine was purulent, and there was a tumor in the right lumbar region. The pelvis of the right kidney was washed out by means of a solution of silver nitrate, 1–1000, and the urine was much improved. The third patient was a man aged thirty-four years who suffered from pains in the right side of the abdomen with chills and fever. There was a large movable tumor in the right lumbar region and catheterization of the right ureter produced purulent urine. The renal pelvis was washed out as in the previous case but the symptoms were not improved, therefore, Casper left the ureteral catheter in position for seventy-two hours, during which time a great amount of almost pure pus was evacuated. After this the condition of the patient gradually improved and at the time of the report the urine was entirely clear. Casper advocated catheterization of the ureter in pyelonephritis as being more satisfactory than nephrotomy, and scorned the idea that reflex anuria is set up by this treatment.

In the discussion of this paper ISRAEL said that nephrotomy was capable of saving a patient who was already profoundly uremic. Catheterization of the ureters could scarcely be expected to succeed under such circumstances. He stoutly maintained the possibility of a reflex anuria and cited the instance of a woman in whom it had several times been produced in periods varying from two to six days, owing to the presence of stone in one ureter. As soon as the stone was loosened or removed the urine began to flow from the opposite ureter as was demonstrated by the cystoscope.

At the session of November 23d, FRANK described "A Case of Paroxysmal Hemoglobinuria." The patient was a woman aged twenty-six years who passed for several years urine containing more or less blood. There was no pain nor any other symptom excepting anemia. All the organs were apparently normal. Both kidneys were palpable, but were not enlarged. With a cystoscope it was easy to make out that bloody urine came from time to time from both ureters. The mixed product was about the color of port wine. Microscopically, one or two red blood-cells were found in ten or twelve fields of the microscope as well as a few epithelial cells and leucocytes and an occasional small cast. The suspicion of hemoglobinuria was verified by the spectroscopic examination. The origin of the trouble was made out with difficulty. Syphilis and malaria were out of the question, and there was no history of poisoning. The sole cause for the trouble was apparently the fact that three years previously the patient had been obliged to work for hours at a time in cold cellars, and she thought that attacks of hemoglobinuria had followed especial exposure to the cold. A test was made one morning in the following way: Having passed urine which was perfectly free from blood, she walked about in her stocking-feet for fifteen minutes in a cold room, and passed urine again. The second specimen was bloody and the diagnosis of paroxysmal hemoglobinuria was confirmed.

STEINER mentioned the case of a man aged thirty-three years whose urine by day was normal, while that passed between 1 and 9 A.M. contained a large amount of albumin, casts, and hemoglobin. This symptom had nothing to do with sleep since when he remained awake at night he passed bloody urine, and if he slept by day the urine remained clear. Numerous examinations failed to demonstrate the presence of animal parasites or germs. The diagnosis remained absolutely obscure.

SENATOR said that various remedies, such as iodid of potassium, quinin, and amyl nitrite, have been advocated as cures of hemoglobinuria, but he had never convinced himself that they were of real value. The sole therapeutic resources seemed to be to protect the individual from cold and to look after his nourishment.

LENNHOFF showed as an instance of traumatic dilatation of the heart a boy aged nineteen years, whose health was good until last August. At that time he was helping to lift a cart, when the horse shied and pinched him between the cart and a lamp-post. He was immediately seized with palpitation and shortness of breath which continued up to the time of report. Whenever he made the slightest exertion, as in stooping, running, or lifting anything, he became extremely cyanotic, with cold hands and feet. The heart dulness as made out by percussion, extended from the left anterior axillary line three-fingers, breadth to the right of the sternum. The impulse of the apex to sight and touch was widely spread out. There were no murmurs. His pulse was irregular and of medium

strength. The diagnosis was that of acute traumatic dilatation of the heart.

MEISSNER spoke of the importance in such cases of recognizing the exact position of the ventricular septum. He said this could be determined by measuring the temperature of the skin. The difference of temperature over the two sides of the heart is considerable. It may reach two or three degrees Celsius (3.6° to 5.4° F.). In cases of dilatation of the heart by determining which ventricle has suffered, we may learn whether hypertrophy or dilatation has taken place.

SENATOR suggested that in the case before them there may have been a hemorrhage into the pericardial sac.

At the Imperial Royal Society of Physicians in Vienna, November 18th, HABART exhibited three soldiers in each of whom a free opening of the pleural cavity had preserved life. The first patient, with suicidal intent, had shot himself in the head four times, had cut his wrist-joint, and stabbed himself in the region of the heart. The last wound was the most serious since it opened the pericardial and left pleural cavities, and tore the lower lobe of the left lung. Habart resected the fifth rib, surrounded the heart with sterile gauze, removed a pint and a half of blood from the pleural cavity, and introduced a layer of gauze between the heart and lungs, and between the heart and the diaphragm. The gauze was left in position until danger from hemorrhage was passed. Recovery was perfect. The second patient was stabbed in a drunken brawl, and as some time had elapsed before operation, both blood and pus were found in the pleural cavity after the sixth and seventh rib had been resected. The cavity was wiped out with sterile gauze and drained with iodoform gauze. This patient recovered with a fistula. The third patient suffered from a streptococcic pleuropneumonia, and was much reduced by chills and high fever. Suspecting a gangrenous focus Habart made a wide opening into the pleural cavity, stripped the exudate from the lung, and scraped out the underlying gangrenous focus. Recovery was perfect.

LORENZ described the results in his hands of Calot's forcible reduction of tubercular deformity of the spine. In order to do away with the great number of assistants required by Calot (three at the head and two at the feet) Lorenz put the child in an extension apparatus, and by means of a screw and pad he exerted slow pressure upon the deformity. Nevertheless, this procedure, just as Calot's method of treatment, was followed by severe paralytic symptoms of the lower extremities, bladder, and rectum, which could only be overcome by the most careful treatment by physicians and nurses for several months. Anatomicaliy, the improvement seemed to be due to circulatory changes which followed the forced extension of the spine. There was no healing in the sense that the gap between the bones became filled up by new bone. It would be unreasonable to expect this, considering the tubercular condition of the vertebræ, and radiographs showed that no such new growth of bone takes place. On this account the deformity usually recurred, and Calot's method of treatment, according to Lorenz, is only indicated in cases of paralysis of the lower extremities which cannot be treated in any other way. Historically, it is an interesting point that Calot is not the discoverer of this method of treatment, but that it was shown to him by a layman, a manufacturer or orthopedic apparatus in Lens, a man named Crud.

SOCIETY PROCEEDINGS.

THE SANITARY CLUB OF BUFFALO.

A Stated Meeting, Held at Buffalo, December 14, 1898.

HENRY R. HOPKINS, M.D., President, in the Chair.

THE President stated that the object of the meeting was the consideration of the sanitation of camps of instruction but, as several of the participants had not understood this limitation, discussion was called for also on camps of mobilization. A circular letter had been sent to governors of States, general military officers and editors of medical journals requesting an expression of opinion as to the advisability of establishing permanent camps of instruction by the Government, each to be fully equipped from a sanitary standpoint and to be occupied as needed. Of a large number of replies, all but two favored such a proposition. Surgeon-General Sternberg asked to be excused from replying definitely, on account of the lack of time to give the matter thought. Brigadier-General H. C. Merriam, headquarters of the Department of California, expressed the opinion that "four such camps ready for occupation in April, would have saved much money and life." Major-General William Montrose Graham, headquarters of the Second Army Corps at Camp Meade, said that "as a rule, camps of State troops allow too much comfort." He ascribed much of the recent suffering in the United States camps to the fact that the troops were not accustomed to hardships and to too great crowding. He expressed gratification that the public was taking an interest in the health of the soldiers.

DR. HOPKINS called attention to the greater responsibility devolving upon the medical officers in the late war as compared with the Civil War. In the latter, we had opinions as to the communicability of typhoid, diphtheria, and dysentery; at present, the work of bacteriologists has replaced these opinions with accurate knowledge. The disregard of the life of the common soldier which had characterized campaigns of the past, especially in Europe, had in it an element of heathenism. "In America, the common soldier is known to be a member of the nobility, the teamster and the company cook are members of the royal family and it is exceedingly important that this royal family of the people should be protected when it takes its life in hand for the defense of the country."

LIEUTENANT PETER C. HARRIS, Quartermaster of the Thirteenth United States Infantry, read a paper on

THE CAMP OF INSTRUCTION.

He emphasized the value of camps of instruction both for the Regular Army and the National Guard and said that they are even more necessary for the instruction of officers than of enlisted men. The raw recruit cannot

keep up with the trained soldier, largely because development of the heart and blood-vessels is deficient. Up to 1894, recruits were drilled for four months at recruiting stations before even being sent to regiments and, after arrival at army posts, two to four-months' additional drill were usually necessary before the recruit could be made available for the routine life of the soldier. For many reasons, this plan, which had been superseded, was the wisest course. The National Guard can scarcely be compared with the volunteer forces of Europe. In England, volunteers can be called out for from two to six weeks annually. In Canada, at least twelve-days' training are given in camp. Continental reserves and other troops that might be compared to the National Guard receive two to four-months' drill, annually. With certain modifications, he thought that the Austrian Landwehr might be taken as a model for the National Guard. Members of the National Guard should have, say, four-weeks' camp instruction during the summer and fall and the members from small towns would need more instruction than those who could have regimental drill at home. In States having only a few regiments it might be well to call out the entire Guard every two years, in order that all troops should have the experience of drilling in considerable numbers and of affording experience for officers. The Guard should be more liberally provided for by Congress and camps should be selected by the ranking surgeon, an officer from line headquarters, and a representative of the quartermaster's department. Speaking of the lessons to be derived from the late war, he said that at Tampa the rations were, at first, issued for thirty days, but this was found inconvenient for the regimental quartermasters, especially as the regimental wagon-trains were cut down below the theoretic minimum. Every regimental quartermaster condemned the attempt to generalize the wagon service and declared in favor of a sufficient regimental wagon-train. By means of diagrams, the various arrangements of regimental camps were shown. As a rule, the nearly square rectangle was preferred, company kitchens on one flank, company and regimental officers on the other, with the sinks of the men and the officers, respectively, on the extreme limits of the flanks, 150 or 200 feet removed from the nearest tents. On some grounds, the slope made it preferable to arrange the camp with four rows of company tents, all facing the same way. This, however, made a very long camp—about 1000 feet. The minimum allowance for small wall tents is six men to a tent. At present, the Thirteenth Regiment (now at Buffalo) has an allowance of a tent for each three men. (The men are quartered in barracks, however.) In the case of a permanent camp, it is well to leave enough space between tents so that they may be shifted every few days without disarranging the plan of company streets. At Tampa the men remained for a week or two in good health and then fever began to develop. The surgeon ascribed this, in part, to the closeness of the tents but it was impossible to change them, on account of the limited amount of space at their disposal. With conic wall tents, about 17 feet in diameter, the minimum allowance is one to seventeen men and, to allow sufficient space, only ten men should be put into one tent. The soil at Tampa was soon polluted and the sinks became offensive as it was impossible to dig them deep enough in the sand.

C. E. P. BABCOCK, Assistant City Engineer of Buffalo and late Major of the Sixty-fifth New York Volunteers, presented a paper on

CAMP SEWERS.

The expense of draining a camp with tile is 33–36 cents per foot for 6-inch pipe; 35–40 cents for 9-inch pipe; 43–50 cents for 12-inch pipe. With the regimental camp arranged nearly in a square, the total cost would be about $1000. To prevent the necessity of digging up the company streets, he thought it better to lay the tile along one flank of the camp, beginning with 6-inch pipe at the officers' sink and ending with 12-inch pipe at a discharge tank two or three hundred feet from the other end of the camp. If wooden tent-floors were used and the streets graded, rain would take care of itself. Four days would be ample time for sewering a camp and only two days would be needed if the regiment included a few members who could lay tile and if the quartermaster's department would issue picks and shovels.

MR. L. H. KNAPP of Buffalo, Assistant Superintendent of the Buffalo Bureau of Water Supply, read a paper on

CAMP WATER-SUPPLY.

The conveyance of water to a camp is rather a matter of convenience than of sanitary necessity. If water is taken from a stream, a dam may be built or an intake tank may be dug. If the soil is porous, it would be better to dig a well near the bank of the stream, to allow filtration. Fords, watering-places and swimming-holes should be located below the water source. Wrought-iron pipe, with screw-joints, could be transported and put into position at any site that would be occupied for more than a few days. The pipe should be buried five feet, and this work, and the placing of a portable pump should not occupy more than twenty-four hours. Thirty-feet pressure would be required to give a fair flow at all taps at once and more than this would allow unnecessary waste. Seventeen taps should be provided, one at each company street, one each at regimental headquarters, officers' mess, guard tents and stable and quartermaster's department. When neither streams nor springs were available, driven wells could be made. Usually, steam would be most convenient for pumping water but, near a large city, electric motors could be used. If windmills were relied upon, a large reservoir would be necessary on account of the uncertainty of power. With a steam-pump, drawing water from a spring or stream near camp, the plant would cost about $4000 and the cost of operation would be about ten dollars a day.

EDWARD CLARK, M.D., of Buffalo then read a paper on

GARBAGE AND SEWAGE DISPOSAL.

He ascribed the terrible death-rate in camps during the Middle Ages to unsanitary measures, particularly the accumulation of excreta. At present, the discipline of the regular army is such that the health of the soldier is

better looked after than that of the average civilian. He pointed out the prime importance of a pure water-supply, even sewage being inadequate without it, as rain cannot be depended upon to flush the drains. The sewers should not discharge into streams but onto the soil, the European system of sewage farms having been proved to be practically innocuous. The burial of garbage, as advised by the Surgeon-General, is a dangerous method on account of the liability of development of a malarial focus. The ideal method of disposing of garbage is cremation. An estimate of expense is impossible because the present plants are in the hands of private contractors who will not give out the actual cost of management.

MR. H. C. GARDNER of Buffalo discussed in his paper the subject of

CAMP WALKS AND STREETS.

He considered concrete much superior to asphalt and also cheaper if a supply of sand and gravel were at hand upon which the regiment could draw without other cost than that of labor. Under these circumstances, it would cost about ten or fifteen cents a square foot. The elongated camp would comprise about 219,705 feet; the condensed camp 141,466 feet. By laying concrete all over the area covered by tents, thorough flushing of the camp would be possible.

M. A. VEEDER of Lyons, N. Y., then read a paper on

THE RELATIVE IMPORTANCE OF FLIES AND WATER-SUPPLY IN SPREADING DISEASE.

From the practical sanitary standpoint, camp diseases can be divided into intestinal and malarial, the former including typhoid and yellow-fever, dysentery and cholera. In camps, malaria is spread almost entirely by water, intestinal diseases almost entirely by flies. The failure of measures directed to the water-supply in the Cuban campaign, he ascribed to this fact. Even now, typhoid is rife in Manila and Honolulu. In the recent campaign in Fashoda, although the climate was especially dry and general conditions as to water-supply favorable, typhoid was the greatest scourge of the army. An epidemic of dysentery was cited, taken in hand when forty cases had developed with ten deaths, the disease having spread from house to house by short leaps. After adopting measures to prevent access of flies, not a single new case developed. The progress of a camp disease by short leaps, should suggest that it was borne by flies while a general dissemination should call attention to the water-supply. Fly-borne epidemics also follow the direction of the wind. In large cities, with general water-supplies, free drainage and absence of privy-vaults, water is the great carrier of disease, whereas, camps, like small villages, have most to fear from flies. For this reason, typhoid is more or less prevalent at all seasons in the cities, usually only in the dry and sultry weather of early autumn in small villages.

He strongly condemned the practice of burying typhoid excrement, citing a series of little epidemics that could be traced to a nurse who had followed this method. After the nurse had herself succumbed to the disease, the epidemics ceased. Typhoid bacilli will penetrate to the surface of the soil, if buried. Disinfection is necessary and, both on account of its color, its permanence after evaporation and efficiency, copper sulphate is to be preferred. In camp, on account of the practical impossibility of diagnosing incipient typhoid, all excreta should be disinfected. The coloration of the ground would show just how far the disinfection had been successful. Volatile disinfectants are not so serviceable as non-volatile. The Government plan of furnishing large, portable, water-tight tanks for use as sinks, is good in theory but scarcely practical. The Indians avoid sickness by frequently moving their camps. Burial of feces could be relied upon to afford protection against infection by flies for a few hours. Boiling would render water safe to drink and, even against malaria, this precaution would afford almost complete immunity as the conveyance of this disease by mosquitoes has been greatly exaggerated. Not only knowledge but discipline is necessary to protect the soldier, and sanitation under the guns of the enemy is a difficult matter.

CAPTAIN NORTON in discussion said that camps should be pitched so as to drain toward the flank, while most that he had seen had been arranged so that the drainage swept from one end to the other. The greatest bulk of sewage was from the sinks, baths, kitchens and hydrants of company streets. Under proper conditions the discharge of sewage into streams is advisable, though not the ideal method.

DR. GREENE in speaking of water-supply gave the preference to spring water, then in order that from deep wells, rivers and lakes, and shallow wells. For permanent camps a filter might be necessary and the only practical method is sand-filtration. He told of visiting a camp during the late war, in which two regimental camps were pitched so that the ground sloped toward their common well.

MAJOR SMITH of the Sixty-fifth New York Volunteers, mentioned Peekskill, N. Y., Mt. Gretna, Pa., and Seagirt, N. J., as ideal camps of instruction. He made a sharp distinction between such camps of instruction and the camps of mobilization about which so much criticism has been offered. Under the circumstances of occupancy, it had been impossible to prevent sickness in the camps, although such matters as policing, disposal of garbage, etc., were within the jurisdiction of the medical officers. (Major Smith, although a surgeon was a line officer in the volunteer army.) Burning garbage would be impossible in the face of the enemy and, at Camp Alger, large heaps of garbage accumulated that were too moist to burn, crematories not being supplied. Burial was therefore necessary. In a camp that had been occupied several months, the disposal of garbage would best be effected by contracting for its removal just as in the case of cities. At Camp Black, the farmers gladly removed the garbage on account of its value as a fertilizer. For the same reason, the owner of the land at Camp Alger would not allow garbage to be removed unless he were paid for it and this deterred those who would willingly have removed it if it had been given to them. Even the removal of bones and fat was stopped. The health of the camp even suffered

because the kitchen attendants were bribed with liquor by some one who wished to get the perquisites of garbage. The sinks, as they became full, were covered over and so much ground was occupied in this way that there was serious danger of a horse plunging into the soft spots and breaking a leg. A middle course had to be adopted regarding sinks. If too near, flies became a source of danger, if put too far away, men, especially with beginning diarrhea would defecate on the way to the sinks. The flies seemed to keep track of mess calls and would swarm from the sinks to mess at the meal times. Unless a camp were pitched like a saddle on a ridge of ground, he did not approve the placing of sinks on both flanks, on account of the double danger of infection in heavy rains. In one instance, he had observed a stream of rain water coursing from the officers' sink directly through one of the tents. Instead of 200 or 300 cases of typhoid in a regiment, as was the case with the Sixty-fifth New York Volunteers (from Buffalo) he felt that practically every one would have suffered if the camp had been occupied a few weeks longer. Disinfectants were not supplied till July and even then they were not to be had regularly.

MAJOR BRIGGS, Surgeon of the Sixty-fifth New York Volunteers, cited the Crimean War, in which the Russians lost 30,000 men from wounds, and 600,000 from sickness. During the Civil War, 104,000 succumbed to wounds, 186,000 to disease. The only war in history in which the number of deaths from wounds exceeded that from disease was the Franco-Prussian, which was short and sharp, fought in a salubrious climate and in which all possible sanitary precautions were taken. Alluding to his own experience as Health Physician when wells were in vogue in Buffalo and to some thoroughly studied epidemics of typhoid, as that at Plymouth, he said that most of the surgeons went into service impressed with the idea that typhoid was a water-borne disease, and that the consideration of flies as a practical factor in etiology had not been thought of till after the epidemics in camp were in progress. The scientific consideration of the water-supply of Camp Alger was like the subject of ophiology in Ireland—there wasn't any. The wells sunk by contractors were put wherever the digging was easiest. The water supplied to the Sixty-fifth Regiment was clear, cold, and odorless, but the drainage of the camp was toward it. A week after camp had been moved and after a hard rain for three or four days, although nothing that could be picked up or swept up had been left behind, there was still a stench from the deserted ground, so thoroughly had the soil been fouled. In the Sixty-fifth Regiment and in some others, the epidemics of typhoid seemed to strike by companies and, for two or three weeks other companies just across a narrow street, having the same food, water, air, and otherwise in the same circumstances, would be free from disease for two or three weeks. (This was explained by Major Smith on the basis of separate milk contracts for the various companies.) The most unsanitary regiment in camp was the Third Virginia. In spite of all discipline, their sinks would overflow in all directions, yet they had the least sickness. The most sanitary regiment was the First Connecticut, and this arrived from service in Maine without a sick man about the first of August, when it had the experience of the regiments previously in camp to serve as a warning. A wholesome spot was selected for their camp and their surgeons adopted every possible sanitary precaution, yet before the Sixty-fifth Regiment left for Buffalo, and within a few days afterward (about the first of September) two train loads of sick were sent home from that regiment. Major Briggs characterized the practice march as an invention of the devil. In a hot, infected country, men would drink and bathe in every water hole that they could find, without regard to its unwholesomeness.

W. W. POTTER, Major and Surgeon, United States Volunteers, reminded the audience of the threefold division of camps, with reference to military hygiene: the permanent camp of instruction, the camp of mobilization, and the bivouac. One of the greatest sources of danger for the soldier is the camp. The economic value of the soldier to the government makes it necessary that the first should be perfect in every detail at whatever direct cost. Eight or ten months are spent in teaching the recruit to keep clean and obey orders but, on a practice march, no amount of discipline will keep the soldiers from drinking where they ought not to. The trained soldier will supply himself with cold coffee or something of the sort in his canteen and will not be so likely to drink impure water as the volunteer. It should be a matter of local pride that the first scientific study of the spread of typhoid infection through excreta was made in Erie County in 1843. The late war was too short to allow great experience to be accumulated. In the 113 days, more men and greater territory were conquered than in a corresponding period in all history. In civil life forty-eight per 1000 die of typhoid, a preventable disease. In August the death-rate for the entire army had reached only forty per 1000.

DR. BENEDICT asked if an estimate could be made of the men in the Sixty-fifth Regiment who were immune to typhoid. In view of the fact that between a sixth and a quarter of the entire regiment had contracted this disease, it would be interesting to know what proportion of those theoretically infectable had failed to contract typhoid.

DR. BRIGGS replied that such statistics were in course of preparation but could not as yet be announced. The figures given of the prevalence of typhoid in the army were somewhat misleading as some of the cases were really of a different nature but all had been grouped together.

MR. WILSON of the Health Department, a veteran of the Civil War, emphasized the influence of the sutler in determining sickness among the soldiers.

REVIEWS.

STUDENTS' HISTOLOGY. A Course of Normal Histology for Students and Practitioners of Medicine. By MAURICE N. MILLER, M.D., late Director of the Department of Normal Histology in the Loomis Laboratory, University of the City of New York. Revised by HERBERT M. WILLIAMS, M.D., Professor of Pathology

and Bacteriology, Medical Department, University of Buffalo. Third Revised Edition. New York: William Wood & Company, 1898.

IN the present edition of this well-known text-book the general plan and arrangement existing in former editions has been preserved, but the subject has been carefully brought up to date, so that a fair presentation of the subject of histology is embodied in the present volume. As an elementary work for the student we know of no better book from which he can obtain all the necessary data for the use of the microscope and for the preparation and examination of normal tissues. All the minor details in microscopical technic are so fully presented that it is a pleasure to the beginner to have before him a book of this nature.

The illustrations are all from pen-drawings by the author and while many are diagrammatic, still they are of much assistance, and are far preferable to some which we have recently observed and which have been directly photographed. On the whole the book is specially commended to all beginners in the study of histology.

HISTOLOGY—NORMAL AND MORBID. By EDWARD K. DUNHAM, PH.B., M.D., Professor of General Pathology, Bacteriology, and Hygiene in the University and Bellevue Hospital Medical College, New York. New York and Philadelphia: Lea Brothers & Co., 1898.

WHEN the rapidity is noted with which new works and revised editions of the older books on this subject have appeared in late years, it is at once significant of an increasing interest in this science and of a demand for reliable books on the subject. The work before us comes under this heading, and, moveover, is unique, in that the histology of diseased processes receives consideration. Part I. is devoted to the normal histology of the various tissues and organs and occupies more than one-half of the volume. The chapter on the cell is especially well handled, and the description of the various processes occurring in karyokinesis is given in a particularly clear and lucid manner so that the average student can grasp the subject without great difficulty. The chapter on the central nervous system receives that care and attention which the recent work in this line demands.

Part II. of the work is devoted to the histology of the morbid processes and the chapters deal successively with degenerations and infiltrations, atrophy, hypertrophy and hyperplasia, metaplasia, structural changes due to and following damage, and tumors. These various subjects are well described and presented in a satisfactory manner.

Part III., and the last part of the work, deals with histologic technic, and we are surprised to find that the author still adheres to the French word *technique*, which is no longer used by the more careful writers. In this part of the book the author has attempted to condense too much information in a few pages, and the result is an unevenness not manifested in the previous chapters. The methods of fixation, hardening, impregnation, embedding, cutting, staining, and mounting are described, also the methods for the examination of urinary sediments, for the preparation of cover-glass smears, for the examination of sputum, and pus, and blood-smears; for the examination of bacteria in cover-glass preparations, and in the hanging drop, all of which procedures are but briefly outlined and more properly belong to works on bacteriology and clinical microscopy.

Throughout the pages are many illustrations, some of which are original while others are borrowed from the very best sources. They all, however, are admirably drawn and produced, and add distinctly to the value of the work. The paper and bookmaking is beyond reproach. The book is worthy of the cordial support of the profession and is creditable alike to author and publishers, and we take much pleasure in commending it not only to students but to teachers as well.

THE PRINCIPLES AND PRACTICE OF MEDICINE. By WILLIAM OSLER, M.D., Professor of Medicine at the Johns Hopkins University. Third edition. New York: D. Appleton & Company, 1898.

THIS, the third edition of this well-known and widely read work has been entirely revised and enlarged. The brilliant author of this splendid treatise justly says that at the present rate of progress in all departments a text-book six years old (the first edition) needs a very thorough revision. This he certainly has given to the third edition, either entirely rewriting or adding as new articles the following subjects: vaccination, beri-beri, the bubonic plague, cerebrospinal fever, pneumonia, Malta fever, yellow fever, dengue, influenza, leprosy, glandular fever, the gonorrheal infections, cancer of the stomach, the gastric neuroses, enteroptosis, the cirrhoses of the liver, jaundice, the diseases of the bile passages, diseases of the pancreas, diseases of the thymus gland, diseases of the spleen, lymphatism, Addison's disease, encephalitis, neurasthenia, erythromelalgia. Other articles show the addition of new material.

The thorough revision which the work has undergone brings the subjects treated up to date in every respect. Not since the appearance of the fine treatise on the "Principles and Practice of Medicine" by Hilton Fagge has England or America produced such a worthy publication. It is no more than just praise to say that Dr. William Osler's text-book is the best book of its kind in the English language, and surpasses in many respects the so-called "systems of medicine" which have appeared in the past few years in such generous profusion.

It is difficult if one were searching to find defects to indicate anything which is wanting in this book yet it seems to the reviewer that some mention should have been made by the author of the presence of the Filatow-Koplik spots on the buccal mucous membrane as an early characteristic sign of measles. The sign is of great importance as it precedes the development of the eruption by at least twenty-four hours, and enables one to isolate a child living in an institution or hospital before the diagnosis of measles would otherwise be made. Thus many epidemics in foundling asylums, hospitals, and other institutions where children are treated may be avoided by examining the mouth for these spots in every suspicious case of coryza.

No praise would be two generous to express the value of this book to students and practitioners, since it supplies all useful knowledge in reference to any subject to which either may refer. We hope that it will periodically receive the same studious revision whenever the progress of medicine demands it.

CLINICAL LECTURES ON MENTAL DISEASES. By THOMAS S. CLOUSTON, M.D., Lecturer on Mental Diseases in the University of Edinburgh. New (fifth) edition. Illustrated. Philadelphia and New York: Lea Brothers & Co., 1898.

THIS text-book, which has passed through so many editions, and in all, despite the contemporaneous publication of innumerable volumes on psychiatry, has maintained its place as a standard work, needs no further notice than the mere mention of its reappearance in an improved form. Dr. Clouston's book has always been recognized as a classic, both for study and for reference.

The author, in avoiding all attempts at an artificial classification of the diseases considered, hits upon a descriptive arrangement which makes the book clinical as well as didactic, simple as well as complete, entertaining as well as instructive. The charming style, so attractive in the previous editions, is not lost in the new one, and, as before, the reader's attention is held through all the chapters, both by the material presented and the manner of its presentation. A set of colored plates has been added and the volume has been made of more convenient size.

NASAL OBSTRUCTION: The Diagnosis of the Various Conditions Causing It and Their Treatment. By W. J. WALSHAM, M.B., C.M. Aberd., F.R.C.S., Eng., Senior Assistant-Surgeon, Lecturer on Surgery, and Surgeon-in-Charge of the Orthopedic Department, St. Bartholomew's Hospital, etc. New York: William Wood & Co., 1898.

THE author has applied to the diagnosis of the conditions which may give rise to nasal obstruction, the method of proceeding from the manifestations of abnormal condition or of impaired function, as they present themselves to rhinoscopic examination, and thus compose a group of signs and symptoms, to which, finally, a diagnostic label is attached. This method of working from the known to the unknown, from the condition of the parts to the disease which they indicate, has been constantly employed by the author as a teacher of general surgery. It is a reversal of the usual plan of first describing the disease and then discussing how it may be diagnosed from similar affections.

The volume under consideration treats of the subject exhaustively, but the repeated enumeration of facts determined by physical examination produces some confusion. To avoid excessive repetition one is obliged to omit whole passages, to skip about from paragraph to paragraph, at the risk of losing logical connex, in accorddance with the author's instructions. For example, on page 56 one reads: "If the obstruction has been attended by profuse attacks of epistaxis, pass on to section 63, otherwise begin below at section 59."

The chapters on the treatment of the various causes of obstruction are separated from those on diagnosis, somewhat complicating matters, while the description of the operative procedures, and especially of the after-treatment, is too brief. The book may well be of service for occasional reference in a special obscure case, as the entire range of nasal and nasopharyngeal diseases, as well as the affections of the accessory sinuses, have been considered.

A TEXT-BOOK OF MECHANO-THERAPY. By AXEL V. GRAFSTROM, B.Sc., M.D., Late Lieutenant in the Royal Swedish Army; Late House Physician, City Hospital, New York. New York: O. M. Foegri & Co., 1898.

THIS small volume is hardly to be taken seriously by the physician for it is rather elementary and lacking in detail. For nurses and students pursuing practical studies in massage it will prove a useful compend. It is illustrated with eleven pen-and-ink sketches.

THERAPEUTIC HINTS.

For Asthmatic Paroxysms.—

℞ Morphinæ sulphat. . . . gr. ⅛–¼
Strychninæ . . . . gr. $\frac{1}{60}$–$\frac{1}{40}$
Hyoscini hydrobromat. . . gr. $\frac{1}{200}$.
M. Sig. One dose.

Treatment of Acne Rosacea. — JUDASSOHN advises the following program: wash the face at night in very hot water, adding borax or soap if there be much sebaceous secretion. Dry carefully and massage with this ointment, the ichthyol and resorcin being increased according to the toleration of the patient:

℞ Ichthyol . . . . *m.* xvi–lxxx
Resorcin . . . . gr. xvi–xlviii
Lanolin . . . . ʒ vi
Ol. olivæ . . . . ʒ iiss
Aq. dest. . . . q.s.ad. ℥ iss.
M. Sig. External use.

In the morning bathe with water, and if the acne be severe apply one of the following antiseptic washes:

1. ℞ Thymol . . . . . gr. viii
Spiritus . . . . . ℥ ii
Aq. dest. . . . . ʒ iii.
M. Sig. External use.

2. ℞ Hydrargyri chloridi corros. . gr. viii
Spiritus . . . . . ℥ ii
Aq. dest. . . . . ℥ iii.
M. Sig. External use.

For Chapped Hands, Face, etc.—

℞ Salol . . . . . gr. xv
Spiritus . . . . . ʒ i
Glycerini } aa . . . . ℥ ss.
Aq. rosæ }
M. Sig. External use.—*Lutaud.*
